METHODS OF PRODUCING APODIZED FIBER BRAGG GRATINGS AND EXAMPLES OF THEIR APPLICATIONS

Łukasz Zychowicz, Jacek Klimek, Piotr Kisala
Lublin University of Technology, Institute of Electronics and Information Technology

Abstract. The paper presents the principle of operation, the structure, applications and methods of producing uniform, chirped and blazed fiber Bragg gratings as well as long period gratings. Finally, several selected methods used to make apodized gratings are listed and described.

Keywords: apodized fiber Bragg grating, uniform Bragg grating, chirped Bragg grating, long-period grating, blazed Bragg grating

METODY WYTWARZANIA I ZASTOSOWANIE APODYZOWANYCH SIATEK BRAGGA

Streszczenie. W artykule omówiono zasadę działania, budowę i zastosowania apodyzowanych siatek Bragga: równomiernych, o zmiennym okresie, długoookresowych i skośnych oraz wpływ apodyzacji na te siatki. Na koniec wymieniono i opisano kilka wybranych metod stosowanych do wytwarzania apodyzowanych siatek.

Słowa kluczowe: apodyzowane siatki Bragga, równomierna siatka Bragga, siatka Bragga o zmiennym okresie, siatka długoookresowa, skośna siatka Bragga

Introduction

At the end of the 1970s, it was noticed that the creation of periodic structures in glass fibers can significantly expand the field of applications of fiber optics [10]. In the 1980s, the first proposals for the use of Bragg gratings began to appear [19], and it was only in the 1990s that their manufacturing technology was sufficiently advanced to apply the gratings practically [6, 21]. The first publications regarding the apodized gratings were published in 1995–1996 [26, 29]. Since then, these gratings have been intensively researched and developed (including uniform, chirped and blazed gratings, and long-period gratings, discussed in detail in the further part of the paper), as evidenced by the large number of published articles, that are mentioned in the following paragraphs.

1. Principle of operation of the Bragg gratings

The optical fiber Bragg gratings feature periodic changes in the refractive index of the optical fiber core. They are produced by removing the coating of the optical fiber, resulting in the jacket being exposed. On the fiber prepared in this way, the fringes are inscribed with laser light at appropriate distances from each other. The grating acts as a selective mirror – it reflects the light of a specific wavelength (the so called Bragg wavelength), while the light with other wavelengths (which do not meet the Bragg condition, defined by equation 1 – the case of the uniform grating) passes practically without losses.

\[
\lambda_B = 2n_{\text{eff}} \cdot \Lambda,
\]

where \( n_{\text{eff}} \) is the effective refractive index of the optical fiber core, and \( \Lambda \) is the period of the grating.

2. Apodization profiles

It was noted that the functionality of the optical fiber Bragg gratings can be significantly improved by using apodization. There is a true apodization and a non-true apodization. Apodization is a technique of eliminating the unfavorable features of the spectrum – the true apodization can effectively eliminated side-lobes in the reflected spectrum [7]. In addition, it was noted improvement of a group delay (GD) responses of the apodized chirped FBG [31] and a shaping of efficiency of the Bragg wavelength harmonics reflection (i.e. reflections at wavelength that satisfy the higher order Bragg condition) [22, 24]. Apodization consists in forcing a suitable, spatial distribution of light intensity from the laser writing the grating. Many apodizing functions are known. Gaussian, cosine, raised cosine, sinc function are the ones most commonly used. In order to obtain an apodized \( T(z) \) profile, one uses a particular transformation [34]:

- Gaussian profile: \( T(z) = \exp \left\{ -a \left( \frac{z-z_0}{L} \right)^2 \right\} \) (2)
- Sinc profile: \( T(z) = \sin \left( \frac{n\pi z}{L} \right) \) (3)
- Hamming profile: \( T(z) = n \left( \frac{1+H}{1+N\cos \left( \frac{n\pi z}{L} \right) \right) \) (4)
- Sin profile: \( T(z) = \sin^m \left( \frac{n\pi z}{L} \right) \) (5)
- Cauchy profile: \( T(z) = \frac{1}{1+\frac{n\pi z}{L}^2} \) (6)

where \( L \) is the length of the grating. Reflection characteristics for selected types of apodized variable period grating profiles are shown in Figure 1.

Fig. 1. Comparison of the refraction spectrum of an unapodized chirped Bragg grating with spectra of apodized gratings [34]

In Figure 1, it can be seen that the spectrum of the grating without apodization takes on a rectangular shape, which makes finding the maximum power very difficult. In the case of a grating with any apodization applied, the maximum of the spectrum can be easily determined.

3. Uniform Bragg gratings

Uniform Bragg gratings (gratings with a constant period and amplitude) are the simplest and most common gratings. The scheme of such grating is shown in Figure 2. It can be seen that the plane of the grating is perpendicular to the axis of the optical fiber. The light (corresponding to Bragg wavelength) is partially
reflected at each grating period, forming a beam reflected in the opposite direction to the introduced light. These gratings are most often produced using the phase mask method, featuring high repeatability.

\[\text{Fig. 2. Scheme of a uniform Bragg grating structure}\]

In Figure 3, it can be observed that apodization has reduced the reflectivity by a small extent, but for that it has minimized the so-called sidebands resulting from multiple reflections from the opposite ends of the grating, which in selected applications turns out to be more important than the reduced reflectivity. The uniform Bragg gratings have found applications in optical telecommunications (dispersion compensation, optical filtering), measurement (especially strain sensors, where the whole spectrum (without sidebands) contains information about the strain distribution [2, 33]), as well as shock wave transducers [27].

\[\text{Fig. 3. Power reflection spectrum for a 6 mm grating: a) no apodization, b) with apodization [13]}\]

4. Chirped Bragg gratings

Non uniform or chirped gratings feature a variable period along the axis of the optical fiber. Waves with shorter lengths are reflected in the segments of the grating where the period is smaller, while longer waves are reflected in segments with longer periods (in accordance with the Bragg's law).

\[\text{Fig. 4. Scheme of the chirped Bragg grating structure}\]

The resulting spectrum of a chirped Bragg grating is closer to a rectangular one for a grating without apodization than for a grating with apodization (as shown in Figure 5). Apodized chirped Bragg gratings are widely used in telecommunications and sensor technology, i.e. in spectrum analyzers [30], chromatic dispersion compensators, where apodization has a positive effect on ripples in group delay response [1, 8, 16], linear edge filters [4].

\[\text{Fig. 5. Power reflection spectrum for a grating: a) with apodization, b) without apodization [13]}\]

5. Long period gratings

Long Period Bragg gratings (LPG) feature only transmissive properties, i.e. coupling of core modes with cladding modes [17]. Because of this, LPGs do not have a reflection spectrum, therefore the transmission spectrum is shown in Figure 7. In the case of LPGs the period is much longer, compared with the other types of FBGs — for the grating in Figure 6, numerically calculated using the OptiGrating environment, the period is 150 μm.

Based on Figure 7, it can be noted that the grating with apodization features less sidebands, but low dynamic range of peaks (dips). If it is necessary to obtain a higher dynamic range of peaks, similar to an unapodized grating, another “a” factor should be used but the increase of index modulation changes can be a better concept. The full width at half maximum (FWHM) is much larger for the apodized grating. In the transmission spectrum of both gratings, further resonance peaks can be seen, which correspond to the subsequent mode couplings of the core mode with the modes in the fiber cladding. In reference [28] it was shown that apodization in the case of LPG makes the most sense for spectral measurements in the range (of spectrum changes) corresponding to higher cladding modes, because there is the greatest noise reduction there, and the disadvantage of apodizing is the decrease in the attenuation of waves with resonance wavelengths.

LPGs are used in sensors of non electrical quantities (strain, temperature, bending) [11], where changes in the wavelengths, at which the power minimum occurs, are measured, as well as in ultrafast optical signal processing [3].

\[\text{Fig. 6. Scheme of the structure and the method of coupling of the LPG modes}\]

\[\text{Fig. 7. Transmittivity as a function of wavelength for an LPG: a) without apodization, b) with the Gaussian apodization profile and the coefficient } a = 0.5\]

6. Blazed Bragg gratings

Blazed Bragg gratings feature an angle between the longitudinal axis of the fiber and the planes of the grating of less than 90°. The light introduced into the core undergoes partial reflection to the outside of the fiber, which results in the passage of a relatively small amount of light through all planes of the grating.
In the Division of Optoelectronics and Teleinformatic Networks of the Institute of Electronics and Information Technology of the Lublin University of Technology many types of apodized Bragg gratings are being produced – figure 9 shows the spectrum of a chirped grating with a blaze angle of 0°, and figure 10 – the spectrum of a chirped grating with a blaze angle of 2.5°. Apodization was imposed by the excimer laser beam distribution (it is approximately a Gaussian profile), and the beam distribution profile is measured using a beam profiler with a BC 106 VIS camera.

The multiple printing of in-fiber gratings (MPF) consists in writing short (4 mm) gratings that overlap each other, so after each print several new grating periods are created. A pulse generating UV laser is used for this. The segment of the fiber where the grating is supposed to be inscribed is placed in a V-shaped glass groove. Precise movement the fiber forward and backward is controlled by a computer. The light source – an interferometer is in a fixed position [15].

Based on the figures above, it can be seen that in the second case, the transmission of the deepest dip is higher than in the first case, and for the smaller wavelengths there are numerous peaks with transmittivity close to twice the transmittivity of the main dip.

Blazed Bragg gratings are used to build spectrometers, erbium doped fiber amplifiers (EDFA) [14]. Bragg gratings are also known to be used for bending sensors [5], spectrum analyzers [30], polarization discriminators [18].

7. Methods of producing apodized Bragg gratings

Apodized fiber optic Bragg gratings are produced using the phase mask method, multiple printing of in-fiber gratings, the moving fiber/phase mask technique, the symmetric stretch apodization method, using phase mask with variable diffraction efficiency method. Furthermore point-by-point method [32] using a CO₂ laser [9] or a UV laser [12] is used to LOG inscription.

The phase mask method is the simplest and most effective technique for producing gratings. It consists in directing a beam of UV light onto a diffraction structure made of quartz glass. For a grating with a particular period A, a phase mask with a period of 2A is required. In order to move the beam of light on the surface of the optical fiber, precise positioning mechanisms are created. This method works very well in the production of uniform and blazed gratings. The selected apodization profile is created by using a properly designed and manufactured lens that focuses the light beam on the fiber [25].

Similar to MPM apodization technique, where phase mask is dithered instead of optical fiber is presented in [20].

The symmetric stretch apodization method (SAM) is a combination of the MPF and MPM methods, so strict synchronization of the fiber and UV beam positioning systems is required. This allows the writing of two gratings in the same place, with the correct phase relation between them. First, the grating is written on a non-deformed fiber and then on a deformed one. The stretching and loosening of the fiber is carried out using a piezoelectric transducers [15]. Figure 13 shows the SAM scheme using a phase mask, which can be replaced with an interferometer.

The phase mask with variable diffraction efficiency is the most reproducibility method. There is constant effective refractive index along the whole grating, so short-wavelength side broadening of spectral characteristic is avoiding in this method. The change of duty cycle and groove depth causes variable diffraction efficiency of the phase mask. The coherent UV laser beam lights up the phase mask and the interference pattern is writing in the fiber core. The technique is working in the case of sources with low coherence, because there is a small distance between the optical fiber and the phase mask [23].
8. Conclusions

The apodization minimizes the side bands of the transmission spectrum for all types of gratings described above. An undeniable disadvantage of apodization is the reduction in the reflectivity of the transmission spectrum, whereas in the majority of applications of Bragg gratings, it is more important to minimize the side bands than to obtain the highest possible main peak, which is still high even for apodized gratings. There are several methods for producing apodized Bragg gratings that are constantly being improved due to the increasingly precise devices used to produce the designed gratings. The use of a phase mask considerably speeds up the process of formation of periodic structures and contributes to their mass production. Nevertheless, for the production of some types of gratings, it is more convenient to use an interferometer (interference method).
