Neolithic deposit of flint cores in Zagórzycy, Kazimierz Wielka district

Abstract: The purpose of this paper is presentation of flint materials from the pit number 92 discovered at multicultural site 1 in Zagórzycy. During the exploration a group of five flint cores were revealed, whose layout indicates an intentional deposit. They were accompanied by few ceramic fragments and several animal bones. In spite of the fact the flint artifacts represented different stages of exploitation, they have a relatively high potential and, after the necessary remedial treatments, could still have been exploited. It seems that the group of cores can be interpreted as a deposit of a utilitarian character. Three of these were formed on the nodule of chocolate flint, the rest were made of Jurassic flint. The size of the obtained blades and the technique of core processing speak for the feature's affiliation to the Lublin-Volhynian culture. Currently, considering only the partial examination of the site 1 in Zagórzycy, making a statement as to whether the presence of the L-VC in the discussed site was only a single episode or had more stable character is sadly not feasible. The reason of separated publication of this deposit is justified since discovery of this assemblage of cores contributes greatly to the picture of flint knapping in the the L-VC.

Keywords: the deposit, the flint cores, the Lublin-Volhynian culture

1 Institute of Archaeology, Jagiellonian University; Gołębia St. 11, 31-007 Kraków, Poland; contact author: barbara.witkowska@uj.edu.pl

1. Introduction

The site 1 in Zagórzycy is located approximately 10 km northeast of Kazimierz Wielka in Świętokrzyskie province, on the area of the Proszowicki Plateau (Kondracki 1978, 365). This part of the region is distinguished by poor soils derived from sands or degraded loesses, which might have considerably influenced settlement instability in the prehistoric and early historical periods of the region. The fieldwork, so far conducted in the valley of the little creek of Zagórzanka, which is one of the tributaries of the Nidzica River, allowed the registering of a series of multicultural sites. The settlement in Zagórzanka valley was concentrated on small promontories, surrounded with what are now boggy depressions. The site 1 in Zagórzycy, best examined in the Zagórzanka valley, also has such a location (Grygiel, Pikulski, 2006 Grygiel et al. 2009a). It is situated
on the top of a promontory (Fig. 1). The excavations were conducted between 2001 and 2008 by Michał Grygiel and Jacek Pikulski within the framework of a long-term research programme of the Institute of Archaeology of the Jagiellonian University (Grygiel, Pikulski 2006; Grygiel et al. 2009a).

Based on field-walking survey we can estimate the size of the site to be approximately 2–3 hectares. So far, an area of 30 ares has been excavated. The excavations have revealed numerous traces of human occupation, dating back from the early Neolithic to the late Middle Ages. The interest of the researchers has thus far mainly been focused on the Bronze Age and Roman Period materials (Grygiel et al. 2009a; 2009b). The preliminary analysis of Neolithic materials led to the distinction of dozens of archaeological features associated with various stages of the settlement in this time, including the Linear Band Pottery culture, the Lengyel–Polgar cycle, the Funnel Beaker culture and the Corded Ware culture. The feature which is described here, as well as the deposit of flint cores, have been mentioned twice in the literature to date: for the first time by P. Kowalczyk (2004) who suggested that the Zagórzyce deposit refers to the oldest phase of Linear Band Pottery culture, and for the second time by M. Kaflinska (2006) who attributed it to the Lengyel-Polgar cycle.

2. Description of the discovery

During the research conducted in 2003 in the northern part of the site (trench LII) feature no. 92 was discovered. Its outline was determined at a depth of 40 cm from the contemporary ground level. The ceiling part of the pit had been destroyed by the cultural layer associated with some of the younger stages of the settlement. The feature was oval in plan, stretched onto the axis NW-SE and with dimensions of approximately 180×100 cm. It resembled a shallow, hollow-shaped pit in profile with an irregular bottom and a maximal thickness which reached up to 20 cm, calculating from the level on which it had been distinguished (Fig. 2). The fill was formed by a dark grey, non-homogeneous layer, considerably disturbed as a result of the activity of burrowing animals. During the exploration in the deepest northwest part of the feature, a group of five flint cores was revealed and whose layout indicates an intentional deposit. They were accompanied by a few ceramic fragments and several animal bones.

3. Flint artefacts

Core number 1. The carinated blade core with separated flaking surfaces in the initial stage of exploitation. The platform was created by utilizing the natural surface which was free of cortex, most likely as a result of thermal fracture. Only at the edge adjoining the flaking surface was it prepared with a series of chip off strikes directed from the
axes of reflection are parallel but with opposite directions. There are visible scars of preparation flakes and platform rejuvenation flakes on the platform next to a small, probably natural surface. The core angle is acute. There are visible narrow blade scars on the rounded flaking surface, including two negatives of short, unsuccessful strikes (hinge), which ended the core’s exploitation. On the edge top, next to bilateral crushing, there are scars of correction strikes being registered, which create the impression of double platform reduction (Fig. 4: 1). The core is made of the three-colour siliceous mass chocolate flint, where streaks of blue colour are visible within. Dimensions: length 4.9 cm, width 5.3 cm, height of the core is 7.5 cm and is equal to the longest blade negative. The width of blades reaches up to 1.6 cm. The weight of the specimen: 175 g.

Core number 3. The single-platform blade core, narrow flaking surface, conical, made of flat concretion of chocolate flint. The sides of the core are partially covered with cortex. The negatives of preparation flakes create a bilateral crest in the rear part. The prepared platform bears traits of rejuvenation. Repair attempts to the platform led to a change in the coring angle for an obtuse. There are visible blade scars on the flat flaking surface, including the results of a striking series which broke the bulging parts of the specimen and whose further course is visible in the form of ruptures. The blades formed that way didn’t detach from the flaking surface (Fig. 4: 2). The edge top bears splinting traits. Maximal width of blade scars ranges from 1 to 1.5 cm. The longest preserved blade scar was 8.2 cm long. Dimensions: length: 5.5 cm, width: 3.3 cm, height of the core: 9.1 cm, weight: 198 g.

Core number 4. The single-platform blade core, wide flaking surface, close to carinated core, made of the G variety Jurassic flint.
One of the sides was initially prepared, on the second the negatives of thermal cracks are visible. The rear edge passes into the cortex surface. The natural platform created by thermal surface utilization, initially prepared only in edge part. The core’s angle is acute. The flaking surface is rounded with traces of trimming, strongly incurved (Fig. 5: 2). The maximal width of blade scars ranges from 1 to 2.7 cm, the longest preserved scar is 108 mm long. The top bears splinting traces. Dimensions: length: 10.2 cm, width: 10.2 cm, height of the core: 11.4 cm, weight: 1116 g.

Core number 5. The single-platform blade block-like core, made of the G variety Jurassic flint. The sides are covered with cortex and bear few negatives of preparation flakes. The rear is partially natural and thermal. In the apex part, a few broad negatives removed from one of the sides are visible. The entirely prepared platform is occupied by negatives of rejuvenation flakes. The edge shows traces of trimming. A slightly convex flaking surface overlaps on the sides. It was probably shortened by the correction of the apex part by several short removals. The core angle is close to straight. An unsuccessful attempt at knapping led to the damage of the flaking surface by a deep scar (Fig. 5:1). Dimensions: length: 11 cm, width: 9.8 cm, the core height: 14.1 cm. Maximal width of the blade scars ranges between 1.4 – 3.3 cm, and the length reaches up to 12.2 cm. Weight: 2121 g.

4. Ceramics

From the fill of the discussed feature, stone artefacts and two ceramic fragments were recovered. Over a dozen further fragments with similar characteristics were recovered from the cultural layer around the feature. This layer is of the same character as in the feature. Even though they all represent uniform technology, the reconstruction of the vessel form was unsuccessful and it is

Fig. 3. Zagórzycze, distr. Kazimierza Wielka, site 1. Core No. 1 made of chocolate flint (drawn by B. Witkowska)
Fig. 4. Zagórzyce, distr. Kazimierza Wielka, site 1. 1 – core No. 2 made of chocolate flint; 2 – core No. 3 made of chocolate flint (drawn by B. Witkowska)
Fig. 5. Zagórzyc, distr. Kazimierza Wielka, site 1. 1 – core No. 4; 2 – core No. 5; both cores made of Jurassic flint of variety G (drawn by B. Witkowska)
uncertain whether the shards come from one vessel. The ceramics found in the fill is a rim fragment with a corrugated verge line and a base fragment (Fig. 6). The lip form and its decoration might be associated with the Lublin-Volhynian culture. Analogical forms are known from the sites in Las Stocki (Zakościelna 1986), Złota (Podkowinska 1953; Rauhut 1962) and also from the nearby settlement in Bronocice (Kruk, Milisauskas 1985). The technology of pottery from Zagórzycze, in which an admixture of sand and crushed stone had been registered, differs from the technology known for the discussed cultural unit. It should be emphasized that all the Neolithic materials known from Zagórzycze associated with the Lengyel-Polgar circle, as well as with the Linearbankeramik, are distinguished by the significant share of mineral admixture as compared to the technological standard observed in the material from sites of Lesser Poland Upland. Perhaps it is the effect of the usage of local materials — the site is located on an elevation built of sandy deposits and presently degraded loess.

5. Cultural affiliation of feature No. 92

A common feature of the presented cores is the manner of their exploitation. In all cases there is a division visible between the active and passive striking platform in the interpretation of Marcin Wąs (Wąs 2005). It is present both in specimens with the platform entirely prepared as well as in that which uses natural planes. The trimming embraces only the at-the-edge part of the platform and serves to correct the flaking angle. The presence of splinting and fractures, which probably arose as a result of leaning the cores against some hard surface during exploitation, is common for all the cores. They are, however, distinguished by their shape going from carinated to conical, dimensions and proportions of obtained half-products, and the extent of the sides and rear preparation.

In addition to some fragments of ceramics, the size of the obtained blades and the technique of core processing, with the explicit traits of Lengyel-Polgar cycle from the phases of post-metric breakthrough, speak for the feature's affiliation to the Lublin-Volhynian culture (Dzieduszyka–Machnikowa, Lech 1976). In the Lublin-Volhynian flint treatment, the predominant types of cores are specimens with a circumferential or rounded flaking surface, parallel to the specimens made of Jurassic flint (Zakościelna 1996, 33–34). They are usually accompanied by cores with narrow flaking surfaces used for the acquisition of small sized half-products. The subsequent similarities concern the poor preparation of the sides and the correction of the flaking surface by splinters spread out from the top. An analogy in the discussed culture can also be found in the incipient core. The block of chocolate raw material, free of preliminary preparation, with one negative of the cortical blade, is known from the sites in Las Stocki, Bronocice and Gródek Nadbużny (Zakościelna 1996, 30–31, Tab. 4).

It seems that the group of cores from feature 92 in Zagórzycze can be interpreted as an intentional deposit of a utilitarian character. Both the context of the find and the character of the collection prove that. Except for core No. 3, formed on a flat nodule, the other artefacts have a relatively high potential and, after the necessary remedial treatments, could still have been exploited (Figs. 7; 8). Presumably for that reason they have been deposited. Flint deposits of a similar character and chronology (Lengyel-Polgar cycle) have been discovered for example

---

2The authors are very grateful to Associate Professor Dr. Anna Zakościelna for her comments related to the pottery technology of the Lublin-Volhynian culture.
in the discussed culture in a model way and links the incipient core discovered in Zagórzycę with it. The longest preserved negative of a blade on this core is 18 cm. A clue to clarify the chronology of the feature could be the raw composition of the collection. The lack of the Volhynian flint in the inventory is probably the result of the cutting the Lublin-Volhynian culture population off from this raw material after its deposits became controlled by the Tripolye culture, as has been proposed by A. Zakościelna (2006) and the expansion of former culture toward west (Fig. 9). The settlement in the Western Lesser Poland Loess Upland is in fact related to the third phase of the development of this unit, which can be dated back to about 3650 BC (Zakościelna 2010, 35).

6. Concluding remarks

The discovery of this assemblage of cores contributes to the greatest extent to the picture of flint-knapping in the Lublin-Volhynian culture. It is known from finished tool forms, especially the sharp, slender blade forms with the characteristic fluted retouch. Among the cores, the conical

Neolithic deposit of flint cores in Zagórzyce, Kazimierza Wielka district

specimens with a single platform are noteworthy (Zakościelna 1996; 2006, 88). The discovery from Zagórzyce significantly emphasises the commitment to the variant created by scaphoid specimens, well known from different groupings of the Lengyel-Polgar cycle (i.a. Dzieduszycka-Machnikowa, Lech 1976). The lack of information about the places where the flint was extracted and processed is still keenly felt, although the significance of this culture in the distribution of artefacts made of Volhynian, chocolate and Jurassic flint from the areas of upper Dnestr basin and upper Vistula towards the south, was undoubtedly considerable.

Currently, considering only the partial examination of the site 1 in Zagórzyce, making a statement as to whether the presence of L-VK in the discussed site was only a single episode or had a more stable character is sadly not feasible.

**Neolityczny depozyt rdzeni krzemiennych z Zagórzyc, stan. 1, pow. Kazimierza Wielka**

Wielkość stanowiska 1 na podstawie badań powierzchniowych można szacować na około 2–3 ha. Do chwili obecnej rozpoznano wykopaliskowo obszar o łącznej powierzchni 30 arów, co czyni to stanowisko najlżej przebadanym w całym wspomnianym kompleksie. Dostarczyło ono licznych śladów osadnictwa datowanych od wczesnego neolitu po późne średniowiecze. Zainteresowanie badaczy skupiało się do tej pory w znacznym stopniu na materiałach z epoki brązu i z okresu wpływów rzymskich, które były sukcesywnie opracowywane i publikowane. Wstępne rozpoznanie materiałów neolitycznych doprowadziło do wyróżnienia kilkudziesięciu obiektów związanych z różnymi etapami młodszej epoki kamienia. Opisywany depozyt był już dwukrotnie wzmiankowany w literaturze: po raz pierwszy przez P. Kowalczyk z sugestią przynależności materiałów do najstarszej fazy kultury ceramiki wstępnej rytej (KCWR), a następnie przez M. Kaflińską z przypisaniem do cyklu lendzielsko-polgarskiego.

Obiekt nr 92 odkryty został w 2003 roku w północnej partii stanowiska, na odcinku LII. Jego zarys wyróżnił się na głębokości 40 cm od współczesnej powierzchni gruntu. Strop jamy został zniszczony.
przez warstwę kulturową związaną z młodszymi etapami osadnictwa. W rzucie poziomym obiekt miał kształt zbliżony do owalu rozciągniętego na osi NW-SE o wymiarach około 180×100 cm. W profilu rysowała się płyta nieckowata jama o nieregularnym dnie i maksymalnej miąższości sięgającej 20 cm. W trakcie eksplozacji, natrafiono na skupisko 5 rdzeni krzemieniowych. Towarzyszyły im kilka fragmentów ceramiki i kości zwierzęcych.

Układ w jakim odkryto materiały wskazuje jednoznacznie na intencjonalny depozyt prawdopodobnie o charakterze użytkowym. Świadczy o tym zarówno kontekst znaleziska, jak i charakter samego zbioru. Trzy z opisywanych artefaktów wykonano na konkrecjach krzemienia czekoladowego, dwa pozostałe z krzemienia jurajskiego. Poza rdzeniem nr 3 uformowanym na płaskiej konkrecji, pozostałe zabytki posiadają jeszcze stosunkowo duży potencjał surowcowy i po wykonaniu niezbędnych zabiegów naprawczych mogły być nadal eksploatowane. Prawdopodobnie w tym też celu zostały zdeponowane. Krzemienne depozyty o podobnym charakterze i chronologii (cykl lendzielsko-polgarski) odnalezione zostały m.in. w Giebułtowie na stanowisku 8, w Krakowie-Mogile na stanowisku 1 (m.in. skład rdzeni zaczątkowych) czy w Krakowie-Pleszowie na stanowisku 48.

Cechą wspólną przedstawionych rdzeni jest sposób ich eksploatacji. We wszystkich przypadkach widoczny jest podział na piętę aktywną i pasywną w rozumieniu M. Wąsa, zarówno na okazach z piętą zaprawioną w całości jak i wykorzystując naturalne płaszczyzny. Zabieg świeżenia obejmuje tylko część przykrawędną pięty i służy korekcji kąta rdzeniowania. Wspólna dla wszystkich rdzeni jest obecność wyłuszczeń i stłuczeń powstałych zapewne w wyniku opierania rdzeni na twardym podłożu w trakcie eksplozacji. Różni je natomiast kształt (od łódkowatego do stożkowatego); rozmiary i proporcje uzyskiwanego półsurowca utrzymujące się w trzech klasach metrycznych oraz stopień zaprawy boków i tylów.

Wobec stanu opracowania materiałów neolitycznych ze stanowiska 1 w Zagórzycach niewiele można powiedzieć o kontekście znaleziska. W chwili obecnej niemożliwe jest stwierdzenie czy obecność KL-W na omawianym stanowisku ogranicza się do pojedynczego obiektu i epizodu osadniczego czy ma bardziej stabilny charakter. Prezentacja powyższego depozytu w ramach osobnej publikacji wynika z wartości, jaką wnosi on do poznania krzemieniarstwa KL-W.

Guidelines for Authors

Aims and scope
Recherches Archéologiques Nouvelle Serie is an archaeological journal issued by the Institute of Archaeology of the Jagiellonian University in Kraków. In a new form, it continues the tradition of the Recherches Archéologiques, published by the Institute of Archaeology JU since 1968. That journal presented mainly field reports from excavations conducted by archaeologists from the Institute. This formula was changed in 2009 to broaden the journal’s scope and open its pages for all researchers. Therefore, a subtitle ‘Nouvelle Serie’ was added and a new volume numbering was introduced.

The journal presents general syntheses, published in the ‘Studies’ section, as well as the analyses of archaeological materials (which should be discussed against a broad, multi-aspectual background), published in the ‘Reports’ section. The contributions may address any aspect of archaeology and any period of prehistory or history, both in the Old and the New World. We look forward to receiving the texts from authors both from Poland and from abroad. Among the contributions accepted are also summaries of MA theses or extracts from them adapted for publication, as well as outstanding papers by students. Basically, there are no restrictions as regards contribution size. Extensive publications which offer a comprehensive and interdisciplinary approach to the discussed issue and which are provided with numerous and adequate illustrations are warmly welcomed. One should note, however, that the journal does not publish reviews. The original version of the journal is the paper version, however all contributions are also freely accessible on-line. The Recherches Archéologiques Nouvelle Serie accepts contributions in all of the so-called congress languages (English, German, French, Spanish and Russian); the preferred language is English.

Submission of mss
The contribution must be submitted both in electronic and paper form (a single printed copy). The electronic version should be a Microsoft Word file in *.doc or *.rtf format. An additional copy in *.pdf format is welcomed. The files should be saved on a CD or DVD and submitted together with the printed copy.

The text must be written in the Times New Roman font at a size of 12 pts with 1.5 line spacing. All margins should be set to 2.5 cm, and all pages should be numbered. It is highly recommended that the contributors avoid undue use of text formatting options, such as word dividing, bolded or underlined words, numbering or bullets, empty lines, different font types, etc. Using such options should be reduced to the necessary minimum.
Suggestions concerning distinguishing certain parts of the text should be given on the margins of the printed copy. It is important that footnotes contain only the necessary additional information. The authors are kindly asked not to automatically generate the footnotes using a text editor, but to attach them as normal text at the end of the paper, marking them in the text with consecutive numbers (introduced from the keyboard, in superscript).

The submitted contribution should consist of the following:

1. Title.
2. Author/s full name/s, together with affiliation, address, e-mail address, phone number and fax number (for each author); when there is more than one author, please indicate the person responsible for contact with the Editorial Board and – after the publication – with the readers.
3. Abstract (up to 300 words, always in English).
4. Keywords (no more than 7).
5. Text (if the text is divided into chapters – which is recommended – their titles must be separated by an additional empty line below and above – the same applies to sub-chapters; chapters and sub-chapters should be given proper hierarchical numbering, introduced manually – please do not use an automatic numbering option in a text editor).
6. Footnotes.
7. Summary in Polish (up to 1200 words; in case of non-Polish author/s this summary will be generated by the Editor).
8. References.
9. Figures, and a complete list of figures with figure captions (in an electronic version, as a separate file).
10. Tables.

**Figures and tables**

A continuous numbering (as ‘figures’, in the language of the paper – e.g. ‘Figure’ or ‘Abbildung’) should be kept for all the illustrations and photographs, in the order in which they are referred to in the text. Please note that the maximum size of a printed illustration will be 130×180 mm. Due to a two-column layout, another available size is 60×180 mm. The contributors are kindly asked to mark (with a pencil, on the printed copy) which illustrations must be printed in a larger format and which may be printed small. The size of numbers and letters within figures (we recommend using Arial font and Arabic numerals) should be adjusted to the illustration size, to make them readable. All drawings should be provided with a clear and adequate linear scale. Apart from the printed copy (with figure numbers marked with a pencil), all the illustrations should also be delivered in electronic form, each figure being a separate file of TIFF format (minimum 600 DPI for black-and-white and grey-scale drawings, minimum 300 DPI for colour drawings or photos) named using the name of the author/first author (e.g. Nowak_Figure1.tiff). Figures should be referred to in the text using Arabic numerals; a reference to a particular part of the illustration should use colon, space and proper number/s or letter/s (e.g. Fig. 31: 12–14 or Abb. 2: 14, 16). A full list of figures, with complete figures captions and explanations should be delivered separately.

Apart from the printed copy, all the tables should be delivered in electronic version as a Microsoft Word file (*.doc or *.rtf); an additional version in *.pdf format is welcomed. The tables may be saved in a single file or as separate files; in both cases the file name/s
should clearly refer to the content – it is desirable that the author’s/first author’s name is used (e.g. Nowak_Tables.doc or Nowak_Table1.doc). Each table must be provided with a headline containing its number and title. Any comments, if necessary, must be placed below the table. Tables should be referred to in the text using Arabic numerals (e.g. Table 3 or Tabelle 1); their numbering should follow the order in which they are referred to in the text.

Please do not forget that the printed copy submitted to the Editorial Board should have illustrations and tables placed separately at the end of the paper and not within the text.

Authors are responsible for obtaining permissions from copyright holders for reproducing any illustrations, figures, or tables previously published elsewhere.

References
The bibliography should only contain positions that are referred to in the text or in the illustrations or tables. Journal names should be used in their full form. References in the text should be ordered chronologically, beginning with the oldest quoted position and kept to the following pattern: (Huntley, Birks 1983, 35–38; Ralska-Jasiewiczowa 2004, 32; Hajnalová 2005). If a publication has more than two authors, the expression et al. should be used (e.g. Bennet et al. 1991). If there is more than one publication of the same author/s within one year, lower case extensions should be used (e.g. Jones 1965a; 1965b; Gardner 2002a; 2002b). Figures and/or tables in quoted publications should be referred to using the following pattern: (Huntley, Birks 1983, fig. 14: 7; Smith 1998, table 6).

The bibliography should be listed according to the patterns presented below. They were drawn up for publications in English. For publications in other languages, the use of upper and lower case, as well as the expressions and denotations like: (in:), (ed.), (eds.), pp., (typescript), should be adjusted to the rules of the given language. Particular attention should be given to provide accurate spelling of authors’ names and publication titles, especially in languages where diacritic marks are common (e.g. Czech, Slovak).

**The contributions should be addressed to:**
Dr hab. Marek Nowak, Institute of Archaeology, Jagiellonian University, Gołębia Street 11, 31-007 Kraków, Poland; e-mail: mniauj@interia.pl

**Procedure of evaluation**
All submitted papers undergo a multi-stage assessment process. At the first stage, a contribution’s compliance with the editorial requirements is assessed by the Editor-in-Chief and the Secretary. Next, a preliminary evaluation of the paper is carried out by the Thematic Editor. Accepted papers are then sent to two independent reviewers who are not employed by author’s/authors’ institutions. The review will be made according to double-blind review process rule.

The “Reviewer Evaluation Questionnaire”, containing criteria of the evaluation is attached to the web page of the journal:

Depending on the reviewers’ opinion, the paper is qualified for print, sent to the author for amendments, or rejected. The papers qualified for print undergo a comprehensive proof-reading procedure and necessary language corrections by a native speaker.
The Cracow Team for Archaeological Supervision of Motorway Construction, sp.j (located Senacka 3, Kraków) is a legal identity appointed by the Institute of Archaeology and Ethnology PAN, Jagiellonian University and The Archaeological Museum in Cracow. The Team – as a sole contractor – carries out from 1996 (on the basis of an agreement with the General Management of Domestic Roads and Motorways) rescue excavations on the line of Motorway A4 under construction in Małopolskie Voivodship.

Results of the research are systematically published in a dedicated series entitled VIA ARCHAEOLOGICA.
THE CRACOW TEAM FOR ARCHAEOLOGICAL SUPERVISION OF MOTORWAY CONSTRUCTION publishes results of the research on the line of Motorway A4 under construction in a dedicated series entitled **VIA ARCHAEOLOGICA**
