The study examined the relationships between work experience and (a) safety perceptions, (b) job satisfaction, (c) compliance with safety management policies and (d) accident frequency. Participants were Ghanaian industrial workers (N = 320). They were divided into 2 cohorts: experienced and inexperienced workers. Workplace safety perceptions were assessed with Hayes et al.'s 50-item work safety scale. MANOVA was used to test for differences of statistical significance. Posterior comparison with t test consistently revealed significant differences between experienced cohorts and their inexperienced counterparts. Experienced workers indicated the best perceptions on safety, expressed the highest level of job satisfaction, were the most compliant with safety procedures and recorded the lowest accident frequency. From a practical perspective, analysing differences in work experience in relation to safety perceptions could be useful for organizations as the workers' experience could indicate a need for special safety programmes for particular groups.

work experience safety perceptions job satisfaction compliance safety management

1. INTRODUCTION

Research on perception of workplace safety began in the early 1980s with Zohar's study [1], and has since received considerable attention in organizational and psychological literature. The perceptions about safety values, norms, beliefs, practices and principles shared by workers in their work environments have been technically termed safety climate [1, 2]. Zohar [1, 3], Cooper and Phillips [2], Prussia, Brown and Willis [4] and others have written about the importance of safety perception surveys. First, as leading indicators of safety performance, they have helped in identifying precursors to accident occurrence, and by so doing, effectively decreased the number of accidents. Second, by providing proactive information about safety problems before they

develop into accidents and injuries, safety perception surveys have provided management with guidance on developing specific safety programmes. Third, compared to other proactive means of accident prevention, safety perception analyses are relatively inexpensive. Finally, they have provided information about safety management from employees' perspectives. With specific reference to the current study, exploring the impact of job experience in a safety climate analysis could provide a potent proactive safety management tool, as they could indicate a need for special safety programmes for a particular group.

Given the critical importance of safety climate and the evidence that it is influenced by organizational and human factors, the extent to which safety perceptions differ in different work groups, companies and institutions has been

meticulously examined for the past 30 years. DeJoy, Murphy and Gershon's analyses in health care settings [5], Diaz and Cabrera's analyses on airport ground handling operations [6] and Niskanen's study on road administration [7] are examples of such studies. Additionally, comparative analyses between managers' and employees' perceptions [4], high- and low-accident organizations [3], individual- and organizational-level climate perceptions [8, 9] and between blue- and white-collar workers [10] have been carried out. What most of these studies revealed is that workers differ in their attitudes to safety issues and in their perceptions of workplace hazards. A body of evidence also links safety perception to safety performance [2, 8], accident frequency [11], job satisfaction [12], compliance with safety management policies [13, 14] and workers' perceptions regarding organizational support [15, 16].

Several publications on workplace injury and safety management point to the increasing importance of workers' demographic variables, particularly job experience (e.g., Carder and Ragan [17], Hansen [18], Fabiano, Currò, Reverberi, et al. [19] and Paul and Maiti [20]). Despite this attention, there is still paucity of research regarding the impact of workers' experience on workplace safety perceptions. The current study was thus designed to extend the study on work experience and safety management. Accordingly, it compared the safety perceptions of workers with two levels of job experience (experienced/inexperienced). Additionally, it investigated the relationship between these experience levels with job satisfaction, compliance with safety management procedures, and accident frequency. The dearth in research on organizational behaviour in the African work environment constitutes another reason for these analyses.

Work Experience in the Accident and Safety Literature

Workers' experience is one of the most extensively researched concepts in the organizational literature. It is regarded as one of the most relevant job characteristics for predicting

job performance, but with some conceptual disagreement. It is sometimes defined in the organizational literature as the job-relevant knowledge gained over time (e.g., Quiñones, Ford and Teachout [21]), and at times as organizational tenure [22, 23]. A considerable body of literature has linked work experience to a range of organizational performances including risk-taking, accident analysis and safety management. Most studies in this domain have focused predominantly on experience-accident frequency relationships, and research specifically designed to explore the relationship between work experience and safety perceptions is lacking.

Research studies designed to investigate the link between work experience and job satisfaction is scanty. Much of the theoretical and empirical research has investigated the association between organizational tenure and job satisfaction, and the conclusions drawn have been deduced from the affective organizational attachment that develops with tenure (e.g., Ambrose and Cropanzano [24] and Wright and Bonett [25]). Through this link, work experience has been found to be a strong predictor of job satisfaction (e.g., Trevor [26] and Carsten and Spector [27]). The argument for this observation is that longevity at work builds up a psychological link between workers and their organizations through which long-tenured workers (experienced) identify with their organizations and experience more positive feelings about their job assignments and work conditions. Consequently, relative to their short-tenured colleagues (inexperienced), long-tenured (experienced) workers expressed greater job satisfaction. This relationship has been confirmed and highlighted in a review by Oshagbemi [28].

However, other researchers have found that longevity at the workplace does not necessarily bring loyalty, commitment and indicate job satisfaction (e.g., Wright and Bonett [25] and Kass, Vodanovich and Callender [29]). Kass et al. found a positive association between job dissatisfaction, boredom, and organizational tenure; they argued that longevity was due to workers being tied to their workplaces and

lacking suitable job alternatives [29]. In essence, longevity cannot be regarded as a consistent indicator of organizational attachment and job satisfaction. There is therefore no obvious basis to expect long-tenured (experienced) workers to express greater job satisfaction than their short-tenured (inexperienced) counterparts.

Studies on the link between work experience and compliance with safety policies is rather inadequate and conflicting. While Zeitlin [30] found overall safety compliance to be highest among the inexperienced, Paul and Maiti [20] in their recent study, did not find any such relationship. By means of multivariate methodology, they recorded that the experienced, as well as their inexperienced counterparts, are likely to disregard safety policies. Research on work experience and accident frequency is rather consistent with a few contradictory findings. While a substantial body of research found that length of job experience was related to decreased accident rates (e.g., Fabiano et al. [19], Barkan, Zohar and Erev [31], Kecojevic, Komljenovic, Groves, et al. [32], Wu, Liu and Lu [33], Siu, Phillips and Leung [34]), a few studies found experience to be positively related to accident frequency (e.g., Hansen [18] and Frone [35]). The principal reason for this observation was the close association between experience and job requirements which entail greater skill requirements, responsibility and exposure to greater accident risk. Yet, other studies have shown that experience per se does not decrease accident frequency independently of age [20, 36]. In an empirical study of three groups of various experience working in the same area and exposed to the same environmental hazards, the relationship between accident frequency and work experience was found to follow the shape of an inverted U [37]. Workers with the least experience (probationary: 1–3 months' experience), and workers with the most experience (incumbents: 12 months' and over) had significantly fewer accidents than workers with intermediate experience (recent hires: 3–12 months' experience). Butani recorded injuries among coal miners to vary more by experience than by age [38]. He noted that

workers were experiencing injuries at the same rate when grouped by age, but not when grouped by experience. According to Paul and Maiti an inexperienced worker is equally likely to be injured as an experienced one [20].

On the basis of this literature review, it is reasonable to expect employees' work experience to have different effects on their safety perceptions, level of job satisfaction, compliance with safe work procedures and accident frequency. Thus the following hypotheses were formulated.

- Hypothesis 1: work experience and safety perception. Because of the absence of ample evidence that bears directly on this relationship, it is tested but no prediction is made regarding its direction.
- Hypothesis 2: work experience and job satisfaction. Despite the irregularities and inconsistencies, it is anticipated that experienced workers would express more job satisfaction than their inexperienced colleagues.
- Hypothesis 3: work experience and compliance with safety work procedures. Because of the absence of ample evidence that bears directly on this relationship and the inconsistencies in the few findings, this relationship is tested but no prediction is made regarding its direction.
- Hypothesis 4: work experience and accident frequency. Despite the irregularities and inconsistencies, it is anticipated that experienced workers would have fewer accidents.

2. METHOD

2.1. Sample and Procedure

Three hundred and twenty Ghanaian industrial workers participated in the study; 32% ($n = 102$) of them were miners, while 68% ($n = 218$) were from textiles, timber and saw-mill plants, breweries, and food-processing plants in the industrial cities of Accra, Tema and Kumasi. Sixty-five percent ($n = 208$) were male and 35% ($n = 112$) female. Thirteen percent ($n = 42$) of all participants had been at the workplace for

less than a year; 22% ($n = 70$) 1–5 years; 21% ($n = 67$) 5–11 years; 25% ($n = 80$) 11–15 years; and 19% ($n = 61$) over 15 years. Regarding age, 22% ($n = 70$) of the workers were 18–29 years old; 25% ($n = 80$) 30–39; 43% ($n = 134$) 40–49, and 10% ($n = 32$) were 50 years old and more. The educational background of the participants was as follows: 50% ($n = 159$) had basic education, 30% ($n = 98$) had secondary education, 17% ($n = 56$) had professional education and 3% ($n = 7$) had university education.

During lunch break, participants responded to a structured questionnaire in English, which took 15–20 min to complete. Supervisors completed the questionnaire unaided, while for illiterate or semiliterate respondents who had difficulty understanding written English, the local language was used via an interpreter. Respondents were assured that their responses would remain anonymous and confidential and that none of their managers were involved in any way in the study. Statistical analyses of the data were carried out with SAS version 8.2.

2.2. Questionnaire

2.2.1. Perceptions of safety climate were measured with the 50-item work safety scale developed by Hayes, Perander and Smecko [39]. Participants responded on a 5-point scale ranging from 1—*not at all* to 5—*very much*. This instrument assesses employees' perceptions on work safety and measures 5 distinct constructs, each with 10 items: (a) work safety (sample item: safety programmes are effective, $\alpha = .96$), (b) co-workers' safety (sample item: pay attention to safety rules, $\alpha = .80$), (c) supervisor safety (sample item: enforces safety rules, $\alpha = .97$), (d) management's commitment to safety (sample item: responds to safety concern, $\alpha = .94$), (e) satisfaction with safety programme (sample item: effective in reducing accidents, $\alpha = .86$).

2.2.2. Work experience was measured in terms of organizational tenure (e.g., Cellier, Eyrolle and Bertrand [22] and Savery and Wooden [23]). It was thus measured with participants' responses to the question: how long have you worked in this organization? Response options were:

(a) 1–12 months, (b) 1–5 years, (c) 5–11 years, (d) 11–15 years, (e) over 15 years. Following previous studies, workers with 1–5 years' tenure were categorized as inexperienced, and those with 5 years and more as experienced.

2.2.3. Age and job role. Respondents indicated their age and job status (supervisor/subordinate) by marking the appropriate choice in response to a dichotomous item on the questionnaire.

2.2.4. Job satisfaction represented workers' overall feelings towards their jobs. It was measured with one-item global measure of job satisfaction [40]. This measure was chosen because single-item measures of overall job satisfaction have been considered to be equally robust and valid as multiple-item measures (e.g., Nagy [41] and Wanous, Reichers and Hudy [42]). Besides, it has been used extensively in the organizational behaviour literature (e.g., Gyekye [12], Poon [43], Harter, Hayes and Schmidt [44]). The measure has five response categories ranging from *extremely dissatisfied* to *extremely satisfied*, corresponding to our 5-point response format 1—*not at all* to 5—*very much*.

2.2.5. Items for *compliance with safe work procedures* were pooled from the literature, and comprised of the following four: Follow safety procedures regardless of the situation, Encourage co-workers to be safe, Use appropriate tools and equipment, Follow the correct procedure. Participants responded on a 5-point scale ranging from 1—*not at all* to 5—*very much* ($\alpha = .80$).

2.2.6. Accident frequency was measured with participants' responses to question in which they were asked to indicate the number of times they had been involved in accidents in the past 12 months. Cases studied were accidents safety inspection authorities classified as serious.

3. RESULTS

Four statistical techniques were employed to explore the relationships between the variables. First, a χ^2 test showed a highly significant relationship between work experience and

education ($\chi^2 = 243.57, df = 12, p < .001$). As reflected in Table 1, the higher the workers' educational attainment, the more experienced they were.

Second, ANOVA computations indicated differences of statistical significance between the two cohorts of experienced and inexperienced workers. Results of the eight dependent variables with work experience groups revealed significant differences for all dependent variables: work safety ($F(4, 296) = 90.55, p < .001$), co-workers safety ($F(4, 290) = 63.48, p < .001$), supervisor commitment ($F(4, 302) = 92.39, p < .001$), management's commitment ($F(4, 300) = 45.25, p < .001$), satisfaction with safety programmes ($F(4, 255) = 83.02, p < .001$), job satisfaction ($F(4, 304) = 43.73, p < .001$), compliance with safety work procedures ($F(4, 296) = 78.21, p < .001$), and accident frequency ($F(4, 299) = 79.22, p < .001$).

In regard to perceptions of work safety, workers with over 15 years' experience perceived their job assignments to be safe (Table 2). Their counterparts with less than a year's experience were the least enthusiastic about the safety levels of their job roles. Workers with over 15 years' experience rated their co-workers' contributions to workplace safety highest. Their inexperienced counterparts (1–12 months) expressed negativity. Again, experienced workers (15+ years) indicated more concern for safety than their supervisors; whereas, their inexperienced counterparts (1–12 months) indicated the least. Experienced workers (11–15; over 15 years) had positive and constructive views concerning management's commitment to safety, and were appreciably enthusiastic about the effectiveness of the safety programmes in place. Meanwhile, their inexperienced counterparts (1–12 months)

TABLE 1. Work Experience of Ghanaian Industrial Workers by Education ($\chi^2 = 243.57, df = 12, p < .001$)

Work Experience	Educational Level (%)

expressed negativity and disapproved of the safety programmes. A similar pattern was observed on the organizational variables. The experienced workers, more than their inexperienced counterparts, expressed more job satisfaction, were more compliant with safety work procedures, and recorded a lower accident involvement rate.

Third, because experience, age, and job role are strongly interrelated, as shown by status-attainment models (e.g., Blau [47]), it was necessary to estimate the effect of work experience in a multivariate analysis (MANOVA), controlling for the effects of job role and age. The interaction model (age \times experience \times job role) was highly significant for work safety ($F(26, 258) = 18.89, p < .001$). The main effects of experience ($F(4, 258) = 30.68, p < .001$), job role ($F(1, 258) = 75.98, p < .001$), and age ($F(3, 258) = 85.87, p < .001$), and the interaction effects of job role and experience were all significant ($F(3, 258) = 4.47, p < .010$). The interaction model for co-worker safety was also highly significant ($F(26, 250) = 14.35, p < .001$). The main effects of experience ($F(4, 250) = 14.47, p < .001$), age ($F(3, 250) = 78.85, p < .001$), and job role ($F(1, 250) = 60.90, p < .001$) were significant, too. Other interactions were not significant.

The interaction model for supervisors' contributions towards safety was also highly significant ($F(26, 264) = 19.53, p < .001$). The

main effects of experience ($F(4, 264) = 17.36, p < .001$), age ($F(3, 264) = 100.70, p < .001$) and job role ($F(1, 264) = 117.75, p < .001$) were significant. No interaction was significant. Management safety practices indicated a highly significant effect ($F(26, 262) = 9.54, p < .001$). Again the main effects of experience ($F(4, 262) = 13.26, p < .001$), age ($F(3, 262) = 44.47, p < .001$), and job role ($F(1, 262) = 43.15, p < .001$) were significant, but none of the interaction effects were. Regarding workers' perceptions on safety programmes, the interaction model was highly significant ($F(25, 221) = 15.01, p < .001$), with the main effects of job role ($F(1, 221) = 41.94, p < .001$), age ($F(3, 221) = 78.44, p < .001$), and experience ($F(4, 221) = 20.38, p < .001$). Other interactions were not significant.

Regarding workers' compliance with safety management procedures, the interaction model (age \times experience \times job role) was highly significant ($F(25, 221) = 12.45, p < .001$), and again the significant main effects were experience ($F(4, 221) = 16.41, p < .001$), job role ($F(1, 221) = 37.94, p < .001$), and age ($F(3, 221) = 65.61, p < .001$). There were no significant interaction effects. The interaction effect for job satisfaction was highly significant ($F(26, 262) = 12.00, p < .001$). The main effects of experience ($F(4, 262) = 62.56, p < .001$), age ($F(3, 262) = 2.77, p < .05$), and job role ($F(1, 262) = 16.06, p < .001$) were significant.

TABLE 3. Descriptive Statistics on Workplace Safety Scale, Work Experience and Organizational Variables ($p < .001$)

Variables	Inexperienced Workers				Experienced Workers					
	1–12 months		1–5 years		5–11 years		11–15 years		>15 years	
	M	SD	M	SD	M	SD	M	SD	M	SD
WSSA	36.05 _a	9.47	35.35 _a	8.89	22.88 _b	7.56	18.39 _b	4.91	17.54 _b	5.52
WSSB	23.13 _a	4.94	26.12 _a	5.10	30.80 _b	5.04	34.17 _b	3.45	34.85 _b	4.35
WSSC	20.52 _a	7.81	22.94 _a	9.19	33.03 _b	9.24	39.83 _b	5.39	43.03 _b	6.93

Notes. WSSA—work safety, WSSB—co-worker safety, WSSC—supervisor safety, WSSD—management attitudes and practices, WSSE—safety programmes; scores on work safety were in reverse order. Means with different subscripts in the same row are significantly different at $p < .001$.

The interaction effect of experience and age was also significant ($F(9, 262) = 2.35, p < .05$), but not the other interaction effects. The interaction model was highly significant for accident frequency ($F(25, 258) = 15.70, p < .001$). The main effects of experience ($F(4, 258) = 89.97, p < .001$) and age ($F(3, 258) = 4.04, p < .01$) were significant, but none of the interaction effects. All in all, the effect of workers' experience was notably high on all these variables.

Fourth, a posterior t test consistently revealed significant differences between the experienced and inexperienced cohorts (Table 3). The experienced workers, compared to their inexperienced counterparts, evaluated their workplace as safer ($t = 18.52, df = 299, p < .001$), saw their co-workers ($t = -15.23, df = 289, p < .001$), their supervisors ($t = -16.31, df = 305, p < .001$), and management as more committed to safety ($t = -12.35, df = 303, p < .001$), were more satisfied with the safety programme ($t = -16.01, df = 258, p < .001$), and with their jobs ($t = -12.47, df = 303, p < .001$), were more compliant with safety work procedures ($t = -15.28, df = 258, p < .001$), and had experienced fewer accidents in the past 12 months ($t = 16.43, df = 298, p < .001$).

4. DISCUSSION

This current study investigated the impact of work experience on workplace safety perceptions by comparing two groups divided according to their experience. It also examined the relationships between work experience, job satisfaction, compliance with safety management policies, and accident frequency. The major finding was an association between workers' level of experience and perception of workplace safety. The more experienced workers had more constructive perspectives regarding safety than their inexperienced counterparts. Additionally, they also expressed the highest level of job satisfaction, complied with safety policies, and recorded the lowest accident involvement rate. Inexperienced workers, particularly those in their first year at the workplace, were the worst perpetrators regarding safety perception, job satisfaction, compliance with safety policies, and accident involvement rate.

The observed positive relationship between experience and safety perception could be explained by the concept of familiarity and perception of hazards. Apparently, the more experienced workers (particularly those with over 15 years of experience) benefited from their longevity with their organizations. They had acquired the specific job-related and organizational relevant knowledge and the awareness of the organization's safety culture.

Additionally, they had gained seniority and moved to safer jobs that rarely exposed them to the risks and hazards that their relatively inexperienced counterparts encountered. In many workplaces, it is not uncommon to find long-tenured and experienced workers act simultaneously as superiors and subordinates in the workplace. Quite often, they deputize for supervisors and assign to themselves the less risky and dangerous jobs, while leaving the more risky and less desirable ones to the new and inexperienced workers.

As anticipated, the finding supported a positive association between work experience and job satisfaction. Workers with 15 years' experience were the most satisfied with workplace conditions. As tenure increased, the workers found a complex job less novel and interesting. These assignments were most often mentally challenging with greater discretion. Field work experience and interactions revealed that they had access to the bureaucratic managerial system, and had more resources at their disposal than their relatively new and inexperienced counterparts. Their perceptions regarding these positive effects and favours from their organizations created a feeling of indebtedness and a corresponding sense of obligation for them to respond positively in return. As a means of reciprocity¹ for the management's recompense, they complied with the safety management policies [16, 45], and subsequently recorded a relatively lower rate of injury involvement.

The observed negative relationship between work experience and accident frequency could be further explained by the strong association between job experience and organizational tenure (e.g., Cellier et al. [22] and Hale and Glendon [46]). According to these findings, awareness of safety, sensitivity to hazardous situations, diligence and assiduousness tend to increase with tenure. The higher longevity at work provided experienced workers with skills, greater organizational knowledge of safe working procedures, which enhanced their job

performance. Hence, they learned to handle successfully unexpected situations, and displayed acumen and prudence in their ability to recognise situational contingencies, carefully appraised them and avoided disaster. Our observations are consistent with previous findings: both older [38] and more recent ones [19, 32, 33].

Furthermore, experienced workers were most often considered as permanent staff and received safety-related training that provided them with greater knowledge and skills regarding appropriate safety behaviours (e.g., compliance with safety policies). As protagonists and enforcers of safety rules, experienced workers were motivated to comply with the organization's safe work procedures to manifest themselves as responsible role models [9, 49, 50]. Workers who possess the requisite knowledge in the very specific organizational context within which hazards are encountered (safety orientation) tend to be more compliant with safety policies (e.g., Probst [13], Probst and Brubaker [14] and Zeitlin [30]).

By contrast, inexperienced workers, particularly those with less than a year's experience, with comparatively less normative knowledge, and less familiarity with the workplace conditions, were at a greater risk of displaying inappropriate and inaccurate safety behaviours. Thus, they misunderstood and violated more organizational safety policies, and hence recorded the highest accident involvement rate. It is not uncommon to also find this category of workers accepting hazardous tasks and working under considerable stressful conditions, such as job and income insecurity, low earnings, and inability to raise workplace issues and concerns: issues which presumably lead to negative perceptions regarding workplace safety, low job satisfaction, and increased vulnerability to accidents.

¹ According to the social exchange [47] and reciprocity theory [48], workers who perceive some form of organizational support from the management are motivated to reciprocate in terms that benefit their organizations.

5. SAFETY IMPLICATIONS AND DIRECTIONS FOR FURTHER STUDIES

The current findings have implications for workplace safety management. Mandatory safety programmes should be put in place for new recruits. This could consist of an integrated approach of education, enforcement and engineering controls which will best protect workers from accidents and injuries. Effective safety education programmes in conjunction with appropriate leadership role (e.g., corrective leadership and supervisory safety practices) will induce positive safety behaviours into subordinate workers on the shop level. Support for this argument comes from Zohar's recent studies in which supervisory monitoring, prioritizing safety over competing goals, and corrective leadership provided complementary modes of influence on safety behaviour [9, 49, 50]. Additionally, management could invest in making their organizations more satisfying and safer. They could do this by implementing fairness perception measures [51, 52], creating job enrichment programmes [53], and providing support to workers beyond what is formally stated in the contractual agreement [54, 55]. These measures would address the noted disfavoured perceptions regarding supervisors' and management's role in safety from the inexperienced workers' perspectives. Ultimately, they would increase workers' job-satisfaction, organizational efficiency and productivity, inspire safe work practices, and thereby decrease accident frequency and its associated high human and social costs.

The primary strength of this study is its empirical disposition as participants were authentic workers. The findings complement previous ones that found a negative association between job experience and accident frequency (e.g., Fabiano et al. [19], Kecojevic, et al. [32], Siu et al. [34], Frone [35], and Salminen [56, 57]), and positive association between experience and job satisfaction (e.g., Oshagbemi [28]). It also supports studies that showed that workers with the requisite knowledge of safe

work behaviours tend to comply with their organizations' safety management policies and subsequently record fewer accidents (e.g., Elangovan, Mohammed and Mohan [58] and Neal, Griffin and Hart [59]). More importantly, it makes novel contributions to the safety literature on the relationship between work experience and safety perceptions, and compliance with safety management policies.

It is, however, limited by its reliance on self-reported instruments. The possibility thus exists for the findings to be distorted by the participants' desire to respond in a consistent manner. However, recent Crampton and Wagner's meta-analytic research indicated that while this problem continued to be regularly cited, the magnitude of distortions could be overestimated [60]. Self-reported measures have been effectively used in workplace accident analyses and safety surveys (e.g., Gyekye and Salminen [15, 61] and Siu et al. [34]). Besides, while epidemiologic reports were found to be faulty, biased and deficient because of poor documentation [62, 63], research reports have found self-reported accident rates to be closely related to documented accident rates [64]. Notwithstanding these limitations, the current study contributes to the growing body of research, which has identified work experience as an important variable for investigation in safety management policies.
