**Abstract:** A sensorless indirect stator-flux-oriented control (ISFOC) induction motor drive at very low frequencies is presented herein. The model reference adaptive system (MRAS) scheme is used to estimate the speed and the rotor resistance simultaneously. However, the error between the reference and the adjustable models, which are developed in the stationary stator reference frame, is used to drive a suitable adaptation mechanism that generates the estimates of speed and the rotor resistance from the stator voltage and the machine current measurements. The stator flux components in the stationary reference frame are estimated through a pure integration of the back electro-motive force (EMF) of the machine. When the machine is operated at low speed, the pure integration of the back EMF introduces an error in flux estimation which affects the performance torque and speed control. To overcome this problem, pure integration is replaced with a programmable cascaded low-pass filter (PCLPF). The stability analysis method of the MRAS estimator is verified in order to show the robustness of the rotor resistance variations. Experimental results are presented to prove the effectiveness and validity of the proposed scheme of sensorless ISFOC induction motor drive.

**Keywords:** Induction motor • Stator flux orientation model • Model reference adaptive system (MRAS) • Rotor speed and resistance estimation • Programmable cascaded low-pass filters (PCLPF)

## 1. Introduction

Indirect flux-oriented control (FOC) techniques are now widely used for the control of induction motor drives in high-performance applications. For the stator-flux-oriented control (SFOC) induction motor drive, the rotor position – using an incremental optical or magnetic encoder sensor placed on the shaft – and information of the current's components are continuously required (Boussak and Jarray, 2006). However, the rotor position sensor leads to reduced reliability and requires additional cabling and space on the shaft. It also increases cost, weight and susceptibility to noise.

To overcome these problems, the use of sensorless control without a mechanical sensor is an attractive solution. Actually, advanced research works focus on the SFOC induction motor drive approach, which independently controls both the torque and the flux without a mechanical sensor. These investigations have been performed during the past few years. They are aimed at the development of the sensorless SFOC featuring a dynamic behaviour comparable or similar to the drives equipped with a mechanical sensor on the shaft. Nowadays, with the progress of power electronics, microcontrollers and digital signal processors (DSPs), sensorless alternating current (AC) motor drives without a mechanical sensor are becoming real in high-performance industrial applications.

Several methods for the sensorless SFOC induction motor drive are presented in the literature, such as the observer-based techniques of artificial neural networks (ANNs) (Nassar and Khoei, 2015; Verma et al., 2014), Luenberger observers (LOs) (Propovic et al., 2014), extended Kalman filter (EKF) observers (Ben ammar et al., 1991; Barut et al., 2012), slidingmode observers (SMOs) (Comanescu, 2015) and fuzzy logic (Abbou et al., 2012; Zahraoui et al., 2016). Most of the sensorless SFOC induction motor drive systems are sensitive to inaccuracies, such as the stator and the rotor resistance. Therefore, they should be estimated online in order to obtain robust control (Hadj Saïd et al., 2011).

In previous works (Agrebi et al., 2007; Agrebi-Zorgani et al., 2010; Dybkowski, 2018; Dybkowski and Orłowska-Kowalska, 2013; Zaki Diab et al., 2016), the MRAS scheme has been used to estimate the speed and the rotor resistance. This control method is presented for the sensorless indirect stator-flux-oriented control (ISFOC) induction motor (IM) drive. Again, a detailed description of the proposed technique and its usefulness are given. More importantly, in a previous study (Agrebi-Zorgani et al., 2010), the performances of simultaneous estimation algorithms are tested by simulations.

This paper investigates the MRAS scheme using only stator current and voltage measurements to simultaneously estimate the speed and the rotor resistance at a very low speed. Initially, a strategy of the SFOC induction motor drive is presented. Then, a theoretical study of the proposed algorithm is given even at low speeds. Afterwards, the stability of the two MRAS estimators is studied. Finally, the proposed method is confirmed with experimental studies, which are conducted on a test bench provided with a chart of real-time control of the type dSpace DS1104 real-time controller board.

This paper is structured in five sections including the first section 'Introduction', as follows. In Section 2, the model of the stator flux orientation is presented. The procedure design proposed for the simultaneous estimation of speed and rotor resistance using the MRAS speed estimation scheme is described in Section 3. Experimental results are shown in Section 4. Finally, a conclusion is drawn in Section 5.

## 2. IM model in the stator-flux-oriented frame

By using the stator flux, the dynamic IM model in a synchronous reference frame is given by Equation 1. Speed control can be ensured by a proportional integral (PI) controller, which cancels the static error and improves the dynamic performances of the closed loop speed. Therefore, we choose an integral proportional (IP) controller, which is different from the PI controller by the fact that it does not present a zero in the closed loop transfer function and offers, thus, a better stability (Jarray, 2000).

The control of the components  $d$ - $q$  currents is ensured by a PI controller, in order to reduce the static error and improve the dynamic performances of the current loops.

$$\begin{bmatrix} \frac{d\phi_{ds}}{dt} \\ \frac{d\phi_{qs}}{dt} \\ \frac{di_{ds}}{dt} \\ \frac{di_{qs}}{dt} \\ \frac{d\omega}{dt} \end{bmatrix} = \begin{bmatrix} 0 & \omega_s & -R_s & 0 & 0 \\ -\omega_s & 0 & 0 & R_s & 0 \\ \frac{1}{\sigma\tau_r L_s} & \frac{\omega}{\sigma L_s} & -\frac{1}{\sigma} \left( \frac{\tau_s + \sigma_r}{\tau_s \sigma_r} \right) & \omega_{sl} & 0 \\ -\frac{\omega}{\sigma L_s} & \frac{1}{\sigma\tau_r L_s} & -\omega_{sl} & -\frac{1}{\sigma} \left( \frac{\tau_s + \sigma_r}{\tau_s \sigma_r} \right) & 0 \\ -\frac{n_p^2}{J} i_{qs} & \frac{n_p^2}{J} i_{ds} & 0 & 0 & -\frac{f}{J} \end{bmatrix} \begin{bmatrix} \phi_{ds} \\ \phi_{qs} \\ i_{ds} \\ i_{qs} \\ \omega \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ \frac{1}{\sigma L_s} & 0 & 0 \\ 0 & \frac{1}{\sigma L_s} & 0 \\ 0 & 0 & -\frac{1}{J} \end{bmatrix} \begin{bmatrix} v_{ds} \\ v_{qs} \\ n_p T_l \end{bmatrix} \quad (1)$$

with:  $\omega_{sl} = \omega_s - \omega$ ,  $\tau_r = \frac{L_r}{R_r}$ ,  $\tau_s = \frac{L_s}{R_s}$  and  $\sigma = 1 - \frac{M^2}{L_s L_r}$ .

### 3. Description of the MRAS technique

The principle of the MRAS estimation technique focuses on the determination of two models: reference and adjustable ones (Fig. 1). The reference and adjustable models, developed in stationary stator reference frame, are used in the MRAS scheme to estimate rotor speed and rotor resistance from measured terminal voltages and currents.

The general idea behind MRAS is to create a closed loop controller with parameters that can be updated to change the response of the system. The output of the reference model is compared with an adjustable observer model. The error is fed into an adaptation mechanism, which is designed to ensure the stability of the MRAS (Agrebi et al., 2007; Agrebi-Zorgani et al., 2010). Thus, the update of the control parameters must be performed based on this error. This strategy allows the parameters to converge to ideal values (Agrebi et al., 2007; Agrebi-Zorgani et al., 2010, 2016).

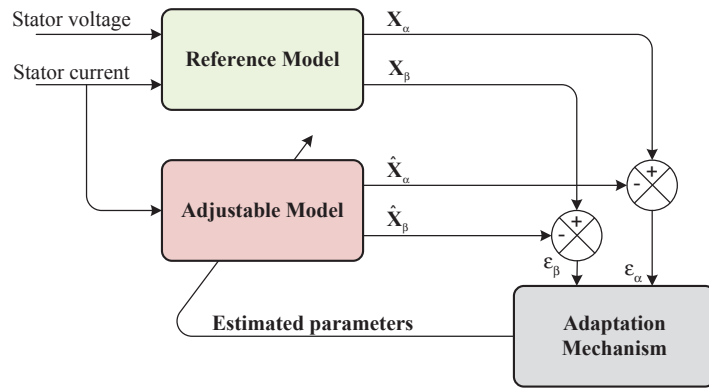

Fig. 1. Synopsis of the MRAS method

#### 3.1 Simultaneous speed and rotor resistance estimation

In order to estimate the rotor speed  $\omega$  and the rotor resistance  $R_r$ , it is wise to use induction motor model in a stationary reference frame  $(\alpha, \beta)$ . This transformation does not call upon the position of the rotor, which is estimated by the MRAS scheme (Agrebi et al., 2007; Kalovsky et al., 2016).

The stator voltages can be described by the following equation:

$$\begin{cases} v_{\alpha s} = R_s i_{\alpha s} + \frac{d\phi_{\alpha s}}{dt} \\ v_{\beta s} = R_s i_{\beta s} + \frac{d\phi_{\beta s}}{dt} \end{cases} \quad (2)$$

The rotor voltages can be described by the following equation:

$$\begin{cases} 0 = R_r i_{\alpha r} + \frac{d\phi_{\alpha r}}{dt} + \omega \phi_{\beta r} \\ 0 = R_r i_{\beta r} + \frac{d\phi_{\beta r}}{dt} - \omega \phi_{\alpha r} \end{cases} \quad (3)$$

with

$$\begin{cases} \phi_{\alpha r} = L_r i_{\alpha r} + M i_{\alpha s} \\ \phi_{\beta r} = L_r i_{\beta r} + M i_{\beta s} \end{cases} \quad (4)$$

Equations (3) and (4) are rewritten under the following new form:

$$\begin{cases} 0 = -L_s D i_{\alpha s} - E i_{\beta s} + D \phi_{\alpha s} + \omega L_r \phi_{\beta s} \\ 0 = E i_{\alpha s} - L_s D i_{\beta s} - \omega L_r \phi_{\alpha s} + D \phi_{\beta s} \end{cases} \quad (5)$$

where  $D = R_r + p\sigma L_r$  and  $E = \sigma L_s L_r \omega$ .

By using Equations (2) and (3), we can identify the speed  $\omega$  and the rotor resistance  $R_r$ . Then, we try to represent the components of the stationary reference frame stator flux ( $\phi_{\alpha s}, \phi_{\beta s}$ ) in terms of accessible stator variables which are the stator currents ( $i_{\alpha s}, i_{\beta s}$ ) and stator voltages ( $v_{\alpha s}, v_{\beta s}$ ). Consequently, two independent stator flux estimators are built. The first is obtained by integrating the Equation (2), the second flux estimators appear by using Equation (5). It is noticed well that Equation (2) does not contain the parameters  $\omega$  and  $R_r$ . Therefore, it can be considered as a reference model of the IM. However, Equation (5) includes the parameters  $\omega$  and  $R_r$ , and it is considered as an adjustable model.

The error between the states of the two models, given by Equation (6), is used to drive a suitable adaptation mechanism that generates the estimation of  $\omega$  and  $R_r$  for the adjustable model. Since the expression of the feedback block  $W$ , which is presented in Equation (7), is different for the speed estimation and rotor estimation, two adaptation mechanisms come up:

- Adaptation mechanism 1
- Adaptation mechanism 2

$$\begin{cases} \varepsilon_\alpha = \phi_{\alpha s} - \hat{\phi}_{\alpha s} \\ \varepsilon_\beta = \phi_{\beta s} - \hat{\phi}_{\beta s} \end{cases} \quad (6)$$

Equation (6) can be presented as follows (Agrebi et al., 2007; Agrebi-Zorgani et al., 2010):

$$p[\varepsilon] = [A][\varepsilon] + [W] \quad (7)$$

where  $W$  is the feedback block, which establishes the input of the linear block.

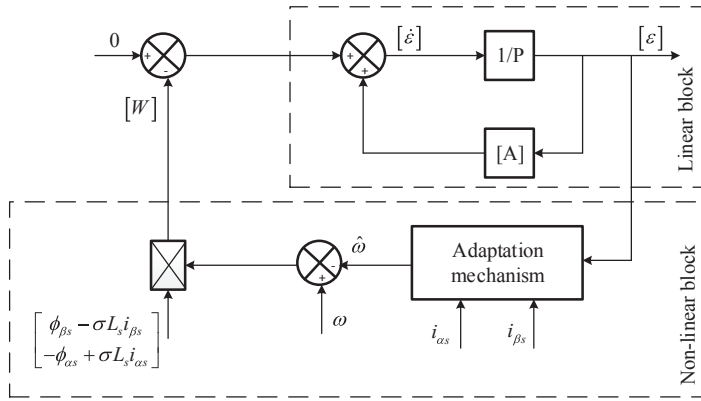

- For the speed estimation

$$A = \begin{bmatrix} -\frac{1}{\tau_r} & -\omega \\ \omega & -\frac{1}{\tau_r} \end{bmatrix} \text{ and } W = W_1 = \begin{bmatrix} -\hat{\phi}_{\beta s} + \sigma L_s i_{\beta s} \\ \hat{\phi}_{\alpha s} - \sigma L_s i_{\alpha s} \end{bmatrix} (\omega - \hat{\omega})$$

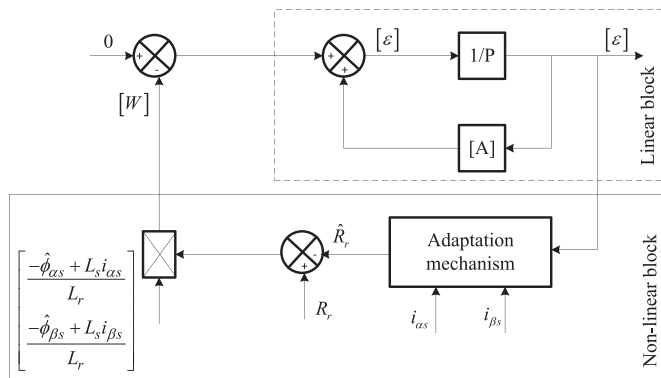

Equations (6) and (7) constitute a non-linear feedback system represented by Fig. 2. Indeed, this system can be schematised by a linear block described by the transfer matrix  $H(p) = (p[I] - [A])^{-1}$  and a non-linear part of the input  $\varepsilon(t)$  and the output  $W(\varepsilon, t)$ .

- For the rotor resistance estimation

$$A = \begin{bmatrix} -\frac{R_r}{L_r} & -\omega \\ \omega & -\frac{R_r}{L_r} \end{bmatrix} \text{ and } W = W_2 = \begin{bmatrix} \frac{-\hat{\phi}_{\alpha s} + L_s i_{\alpha s}}{L_r} \\ \frac{-\hat{\phi}_{\beta s} + L_s i_{\beta s}}{L_r} \end{bmatrix} (R_r - \hat{R}_r)$$

**Fig. 2.** Non-linear feedback system for speed estimation

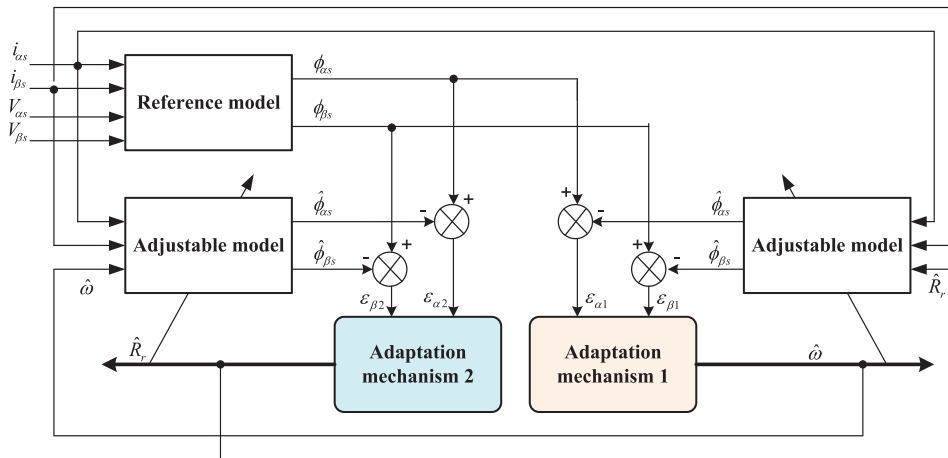

**Fig. 3.** Non-linear feedback system for rotor resistance estimation

Equations (6) and (7) constitute a non-linear feedback system represented by Fig. 3. Indeed, this system can be schematised by a linear block described by the transfer matrix  $H(p) = (p[I] - [A])^{-1}$  and a non-linear part of the input  $\varepsilon(t)$  and the output  $W(\varepsilon, t)$ .

The estimation technique involves use of the adaptation Mechanism 1 to estimate the rotor speed. Subsequently, the adaptation Mechanism 2 is used to estimate the rotor resistance Fig. 4.

The values of speed and rotor resistance are provided at each calculation step for speed and current regulators of the control block.

**Fig. 4.** Structure of the simultaneous speed and rotor resistance estimation by MRAS technique

The asymptotic operation of the adaptation mechanism is fulfilled by a simplified condition, which is  $[\varepsilon(\infty)]^T = 0$ . To be regarded as hyper-stable, the system of negative feedback must satisfy the inequality of Popov (Schauder, 1992):

$$\int_0^{t_1} [\varepsilon]^T [W] dt \geq -\gamma^2 \quad \text{for all } t_1 \geq 0 \quad (8)$$

where  $\gamma$  is a negative constant.

### 3.2 Speed adaptation mechanism

The general structure of the adaptation Mechanism 1 shows that the estimated speed  $\hat{\omega}$  is a function of the error  $[\varepsilon]$ . Indeed, it can be written down as follows:

$$\hat{\omega} = \frac{1}{p} A_1 + A_2 = \int_0^{t_0} A_1([\varepsilon_1]) dt + A_2([\varepsilon_1]) \quad (9)$$

where  $A_1$  and  $A_2$  are non-linear function of  $\varepsilon\alpha_1$ , and  $\varepsilon\beta_1$ , respectively.

By using the expression of  $W$ , Equation (8) becomes equivalent to the following:

$$\int_0^{t_0} \left\{ \left[ \varepsilon_{\alpha 1} \left( -\hat{\phi}_{\beta s} + \sigma L_s i_{\beta s} \right) \right] + \left[ \varepsilon_{\beta 1} \left( \hat{\phi}_{\alpha s} - \sigma L_s i_{\alpha s} \right) \right] \right\} (\omega - \hat{\omega}) dt \geq -\gamma^2 \quad (10)$$

$$\text{with: } \begin{cases} A_1 = K_2 \left[ (\hat{\phi}_{\beta s} \hat{\phi}_{\alpha s} - \phi_{\alpha s} \hat{\phi}_{\beta s} - (i_{\alpha s} \varepsilon_{\beta 1} - i_{\beta s} \varepsilon_{\alpha 1}) \sigma L_s) \right] \\ A_2 = K_1 \left[ (\hat{\phi}_{\beta s} \hat{\phi}_{\alpha s} - \phi_{\alpha s} \hat{\phi}_{\beta s} - (i_{\alpha s} \varepsilon_{\beta 1} - i_{\beta s} \varepsilon_{\alpha 1}) \sigma L_s) \right] \end{cases}$$

where  $K_1$  and  $K_2$  are called adaptation gains, which are constants and positive.

Equation (9) is built around a PI regulator. Fig. 5 represents the result of the synthesis of the speed regulator (Agrebi et al., 2007; Agrebi-Zorgani et al., 2010).

**Fig. 5.** Synthesis of the speed corrector

To study the dynamic response of the speed estimated by the MRAS method, it is necessary to linearise the stator and the rotor equations around an operating point. Thus, the error variation  $\varepsilon$  is expressed as follows (Agrebi et al., 2007; Agrebi-Zorgani et al., 2010):

$$\Delta \varepsilon = \frac{\phi_{\alpha s 0} \Delta \hat{\phi}_{\alpha s 0} + \phi_{\beta s 0} \Delta \hat{\phi}_{\beta s 0}}{\sqrt{\phi_{\alpha s 0}^2 + \phi_{\beta s 0}^2}} - \frac{\hat{\phi}_{\alpha s 0} \Delta \hat{\phi}_{\alpha s 0} + \hat{\phi}_{\beta s 0} \Delta \hat{\phi}_{\beta s 0}}{\sqrt{\hat{\phi}_{\alpha s 0}^2 + \hat{\phi}_{\beta s 0}^2}} \quad (11)$$

The transfer function representing the variation ratio  $\Delta \varepsilon$  compared with  $\Delta \hat{\omega}$  is written as follows:

$$\left. \frac{\Delta \varepsilon}{\Delta \hat{\omega}} \right|_{\Delta \omega \rightarrow 0} = \frac{(p + \beta_r) \phi_0^2}{((p + \beta_r)^2 + \omega^2)} \quad (12)$$

In a steady operation, one will have the following equalities:

$$\phi_0^2 = \phi_{\alpha s 0}^2 + \phi_{\beta s 0}^2 \quad \text{and} \quad \omega = \hat{\omega}$$

Then, by neglecting the effect of the slip pulses  $\omega_{sl}$ , the transfer function of  $G_1(p)$  will be as follows:

$$G_1(p) = \frac{\phi_0^2}{p + \frac{1}{\tau_r}} \quad (13)$$

Hence, the transfer function of the direct chains is written as in Eq. (14):

$$F(p) = \frac{\phi_0^2 (K_1 p + K_2)}{\left(p + \frac{1}{\tau_r}\right) p} \quad (14)$$

We chose an optimal damping coefficient ( $\xi = 0.7$ ) to determine the parameters  $K_1$  and  $K_2$  of the PI corrector.

The transfer function  $F(p)$  of the speed estimator using the MRAS scheme is influenced by the induction motor parameters, the PI regulator coefficients  $K_1$  and  $K_2$ , and the real speed. To highlight the influence of the real speed on the stability of the estimator, the place of the zeroes and the poles for various values of  $\omega$  are presented.

For a rotor speed variation in the interval from 0 to 314 rad/s, the MRAS estimator poles' locations are shown in Fig. 6.

**Fig. 6.** Evolution of the MRAS estimator poles and zeros according to the speed

We note that the variation speed does not affect the stability of the system.

### 3.3 Rotor resistance adaptation mechanism

The general structure of the adaptation Mechanism 2 shows that the estimate of the rotor resistance  $\hat{R}_r$  is a function of the error  $[\varepsilon]$ . Indeed, it is given by the following expression (Agrebi et al., 2007; Agrebi-Zorgani et al., 2010):

$$\hat{R}_r = \frac{1}{p} A_3 + A_4 = \int_0^{t_0} A_3([\varepsilon_2]) dt + A_4([\varepsilon_2]) \quad (15)$$

where  $A_3$  and  $A_4$  are non-linear functions of  $\varepsilon\alpha_2$  and  $\varepsilon\beta_2$ , respectively.

Using the expression of  $W_2$ , Equation (8) becomes equivalent to the following expression:

$$\int_0^{t_0} \left\{ \left[ \varepsilon\alpha_2 \left( \frac{-\hat{\phi}_{\alpha s} + L_s i_{\alpha s}}{L_r} \right) \right] + \left[ \varepsilon\beta_2 \left( \frac{-\hat{\phi}_{\beta s} + L_s i_{\beta s}}{L_r} \right) \right] \right\} (R_r - \hat{R}_r) dt \geq -\gamma^2 \quad (16)$$

$$\text{with: } \begin{cases} A_3 = K_4 \left[ \left( \frac{-\hat{\phi}_{\alpha s} + L_s i_{\alpha s}}{L_r} \right) \varepsilon_{\alpha 2} + \left( \frac{-\hat{\phi}_{\beta s} + L_s i_{\beta s}}{L_r} \right) \varepsilon_{\beta 2} \right] \\ A_4 = K_3 \left[ \left( \frac{-\hat{\phi}_{\alpha s} + L_s i_{\alpha s}}{L_r} \right) \varepsilon_{\alpha 2} + \left( \frac{-\hat{\phi}_{\beta s} + L_s i_{\beta s}}{L_r} \right) \varepsilon_{\beta 2} \right] \end{cases}$$

where  $K_3$  and  $K_4$  are called adaptation gains, which are constant and positive.

Eq. (17) presents a transfer function that connects  $\Delta\varepsilon$  with  $\Delta\hat{R}_r$ :

$$\left. \frac{\Delta\varepsilon}{\Delta\hat{R}_r} \right|_{\Delta R_r \rightarrow 0} = \frac{(p + \delta_0) \left( |\phi_0|^2 - L_s (\phi_{\alpha s 0} i_{\alpha s 0} + \phi_{\beta s 0} i_{\beta s 0}) \right)}{L_r \left( (p + \delta_0)^2 + \omega^2 \right) |\phi_0|} \quad (17)$$

In a steady operation, one will have  $\phi_0^2 = \phi_{\alpha s 0}^2 + \phi_{\beta s 0}^2$  and  $R_r = \hat{R}_r$ .

The functional diagram in the closed loop of the rotor resistance estimation by the MRAS method is given by Fig. 7.

**Fig. 7.** Functional diagram of the rotor resistance estimation

In this functional diagram, the expression of  $K$  is given by Eq. (18) (Agrebi-Zorgani et al., 2010):

$$K = \frac{|\phi_0|^2 - L_s (\phi_{\alpha s 0} i_{\alpha s 0} + \phi_{\beta s 0} i_{\beta s 0})}{L_r |\phi_0|} \quad (18)$$

$$G_2(p) = \frac{p + \frac{R_r}{L_r}}{\left( p + \frac{R_r}{L_r} \right)^2 + \omega^2} \quad (19)$$

Two complex poles ( $p_1$  and  $p_2$ ) are presented in the transfer function  $G_2(p)$ :

$$p_1 = -\frac{R_r}{L_r} + j\omega \quad (20)$$

$$p_2 = -\frac{R_r}{L_r} - j\omega \quad (21)$$

The real part of the two complex poles  $p_1$  and  $p_2$  are negative. Thus, the stability of the function is confirmed. Again, the use of a PI regulator enabled us to obtain a fast convergence and a null static error in the steady state operation.

**Fig. 8.** Locations of poles and zeroes of  $G_2(p)$

The layout of the roots locations related to the transfer function  $G_2(p)$  for 157 rad/s is given in Fig. 8, which characterises the dynamics of the control system. In fact, this function has two poles and a zero, which are all located in the left half-plan of the complex plan. The poles  $p_1$  and  $p_2$  are complex conjugate poles and located at  $-5.94 \pm 157j$ . Their locations characterise the dynamics of the system. Thus, to ensure a good tracking performance and a fast transient response, the zero placement of the PI regulator must be located on the real axis at  $-5.94$  (located on the left half-plan). Consequently,  $K_3$  must be taken of a rather large value and the ratio  $K_4/K_3$  must be equal to the negative real part of the complex poles of the systems (Zaky, 2011, 2012) ( $K_3 = 500$  and  $K_4/K_3 = 5.94$ ). This allows us to have an error of the rotor resistance that decreases the fast exponential form with time without oscillation (over-oscillation or under-oscillation).

**Fig. 9.** Locations of poles and zeroes of  $G_2(p)$  for different values of  $R_r$

The zero location of the controller PI ( $K_4/K_3$ ) can be selected for the value of the rotor resistance given by Fig. 9. In other words, this figure shows the location of the poles of  $G_2(p)$  with various values of  $R_r$ .

### 3.4 Stator flux estimation

In the reference model, and according to system Equation (2), the two fluxes  $\phi_{\alpha s}$  and  $\phi_{\beta s}$  are determined through the integration of the back electromotive force (EMF) of the machine. The estimated flux is obtained by a pure integration and can cause significant problems, in particular, at low frequency due to the noise sensor, the voltage shift (direct current [DC] offset), and the uncertain parameters. In order to overcome these problems, the pure integrator is replaced with a low-pass filter (LPF) (Ghaderi and Hanamoto, 2011). In this paper, we propose to replace the pure integrator with a programmable cascaded low pass filter (PCLPF). This approach has already been proposed to control the IM without a mechanical sensor (Ghaderi et al., 2006). Indeed, a PCLPF includes a few

blocks of these filters. Each block decreases the effect of the voltage shift (DC offset). In one PCLPF, their gains as well as their cut-off frequencies are given according to the stator frequency.

Accordingly, two methods are proposed. In the first method, which is called a modified programmable cascaded low-pass filters (MPCLPF), the estimate precision is improved by eliminating the gain in the calculation phase. In the second method, which is called the extended PCLPF (EPCLPF) (Ghaderi et al., 2007), the estimator behaviour is modified by the elimination of the gain  $G$  in the calculation phase and the extension low-pass filter stages (LPF stages). This method can be applied only to the area of very low speed.

### 3.4.1 Modified programmable cascaded low-pass filter (MPCLPF)

To calculate the phase,  $\theta_s$ ,  $\phi_{\beta_s}(p)$  must be divided by  $\phi_{\alpha_s}(p)$ . However, in the terms  $\phi_{\alpha_s}(p)$  and  $\phi_{\beta_s}(p)$ ,  $G$  is a common factor, so it can be eliminated by simplification. This approach is illustrated below:

$H'(p)$  which is defined as the transfer function of MPCLPF is given by Equation (22).

$$H'(p) = \left( \frac{1}{\tau \cdot p + 1} \right)^3 \quad (22)$$

$$F_{\alpha}(p) = (v_{\alpha s}(p) - R_s i_{\alpha s}(p)) H'(p) \quad (23)$$

$$F_{\beta}(p) = (v_{\beta s}(p) - R_s i_{\beta s}(p)) H'(p) \quad (24)$$

$$\theta_s = \tan^{-1} \left( \frac{F_{\beta}(t)}{F_{\alpha}(t)} \right) = \tan^{-1} \left( \frac{\ell^{-1}(F_{\beta}(p))}{\ell^{-1}(F_{\alpha}(p))} \right) \quad (25)$$

### 3.4.2 Extended programmable cascaded low-pass filter (EPCLPF)

As previously mentioned, the reduction of the continuous voltage shift (DC offset) is an effective means for the sensorless control in the low-speed region (Ghaderi et al., 2007). As the output depends on the gain of the PCLPF, this last should be reduced. Here, it is necessary to take the relation between the amplitude of the gain and the order of the PCLPF into account. For a number of  $N$  LPF stages presented in Fig. 10, the time constant of the filters, the gain and the transfer function are calculated as follows:

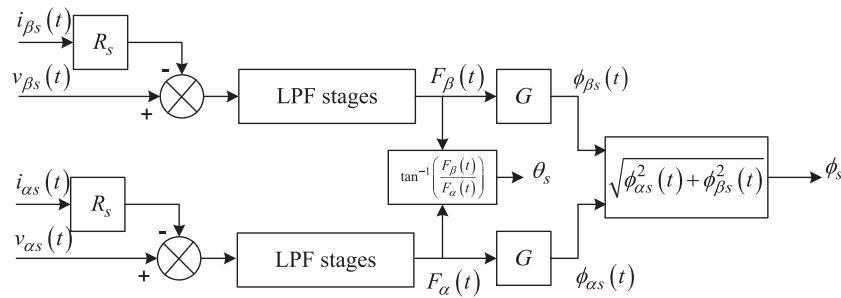

$$\tau = \frac{1}{\omega_e} \tan \left( \frac{\pi}{2 \cdot n} \right) \quad (26)$$

$$G = \frac{1}{\omega_e} \sqrt{[1 + (\omega_e \tau)^2]^n} \quad (27)$$

By using the expression (26), Equation (27) becomes as follows:

$$G = \frac{1}{\omega_e} \sqrt{[1 + \tan^2 \left( \frac{\pi}{2 \cdot n} \right)]^n} \quad (28)$$

$$H(p) = G \left( \frac{1}{\tau \cdot p + 1} \right)^n \quad (29)$$

**Fig. 10.** Diagram of N floors of programmable low-pass filter.

## 4. Experimental results

To validate the performance of estimation of the simultaneous parameters, a prototype implementation of the sensorless ISFOC of an induction motor drive was carried out. Experimental tests were done based on the estimation scheme for sensorless ISFOC of an induction motor, which is proposed in Fig. 11. As a matter of fact, the experimentation has been achieved by using MatLab-Simulink and dSpace DS1104 real-time controller board. The experimental set-up is composed of squirrel-cage IM a 3 kW (Table. 1), a pulse-width modulation (PWM) signal to control the power modules generated by dSpace system, a voltage source inverter (VSI) and a load generated through a magnetic power brake coupled with the three-phase induction motor. The DC link voltage, stator phase currents and voltages are measured by Hall-type sensors.

In order to demonstrate the effectiveness and the robustness of the proposed method, we try out the system for the following operating modes:

- A speed reference of 15 rpm, before applying a rated load torque (20 Nm) at  $t = 7$  s, and cancelling that at  $t = 13$  s.
- A speed reference of 15 rpm by inverting the rotation direction at the instant  $t = 9.5$  s.
- The first case: a preset speed of 15 rpm, followed by the application of a load torque at  $t = 7$  s, and the abolition of the latter at  $t = 13$  s.

**Fig. 11.** Experimental set-up

**Table 1.** Induction motor parameters

Specification		Parameters	
Rated power	3 kW	$R_s$	2.3 $\Omega$
Rated voltage	380 V	$R_r$	1.55 $\Omega$
Rated current	6.6 A	$L_s, L_r$	0.261 H
Rated frequency	50 Hz	$L_M$	0.245 H
Number of pole pair	2	$J$	0.02 kg.m <sup>2</sup>
Rated speed	1430 rpm	$f$	0.0007 Nm.s.rad <sup>-1</sup>

The experimental tests, illustrated by Fig. 12(a), show that the estimated speed and the actual speed converge to that of the reference. The error between the estimated and the actual sizes is presented by Fig. 12(b), and it does not exceed 2 rpm in the steady state. This value of the error is important because of the sensor reliability, which is used to measure the actual speed. However, the velocity sensor used in our application is an incremental encoder with 1,024 pulses per revolution. For a low-speed operation, the velocity precision decreases. Consequently, the error between the real and the estimated rotor speeds increases.

Fig. 12(c) shows the curves of the estimated rotor resistance  $R_r$  and those of the reference. The convergence of the estimated size of  $R_r$  to its reference is proved by Fig. 12(d), representing the error between the estimated and the reference sizes.

Furthermore, Fig. 12(e) confirms the proportionality between the  $q$ -axis stator current and the electromagnetic torque. Knowing that, the measurement of the stator current is used to estimate the electromagnetic torque. The fluxes  $\phi_{\alpha s}$  and  $\phi_{\beta s}$  are presented in Fig. 12(g); it shows that they are in a quadratic phase. The curves of the  $d$ -axis and  $q$ -axis stator currents are given by Fig. 12(f). Finally, the stator currents  $i_{\alpha s}$ ,  $i_{\beta s}$  and  $i_{cs}$  are presented in Fig. 12(h).

- The second case: a pre-set speed of 15 rpm by inverting the rotation direction at the moment  $t = 9.5$  s.

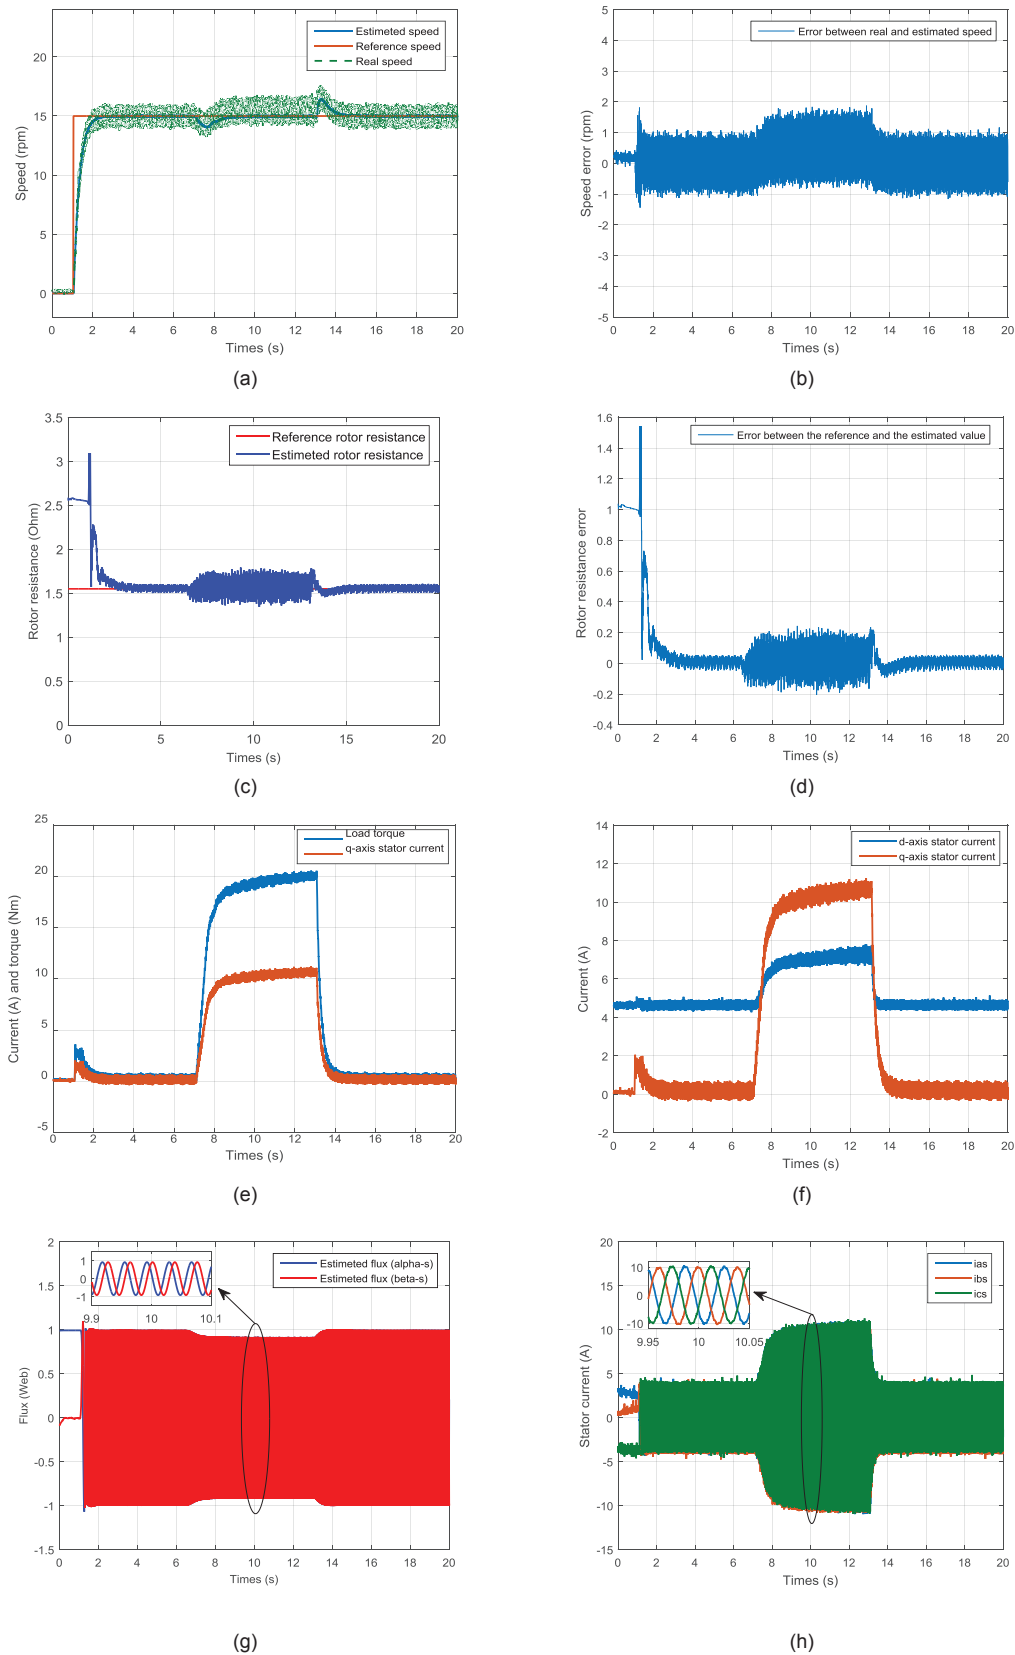

In Fig. 13, the sensorless speed reversal tests are carried out to show the robustness of the proposed scheme for the sensorless ISFOC induction motor drive and the behaviours of the motor during speed transients. In Fig. 13(a), the speed reversal test is performed, from which one observes that the speed estimation and the actual speed converge to that of the reference. The error between the estimated and the actual sizes is presented in Fig. 13(b), and it does not exceed 2 rpm in the steady state. Note that, this error can be  $<1$  rpm if the actual value is measured by a more precise incremental encoder.

Fig. 13(c) shows the curves of the estimated rotor resistance and those of the reference. The convergence of the estimated size of rotor resistance  $R_r$  to its reference is proved by Fig. 13(d), representing the error between the estimated and the reference values, while Fig. 13(e) indicates that even for low speeds the fluxes  $\phi_{\alpha s}$  and  $\phi_{\beta s}$  are in a quadratic phase. However, the convergence of the estimated size of  $i_{qs}$  stator current to its reference is proved by the Fig. 13(f), the same can be said for Fig. 13(g), which presents the  $i_{ds}$  stator current. Finally, Fig. 13(h) shows the stator currents  $i_{\alpha s}$ ,  $i_{\beta s}$  and  $i_{cs}$ .

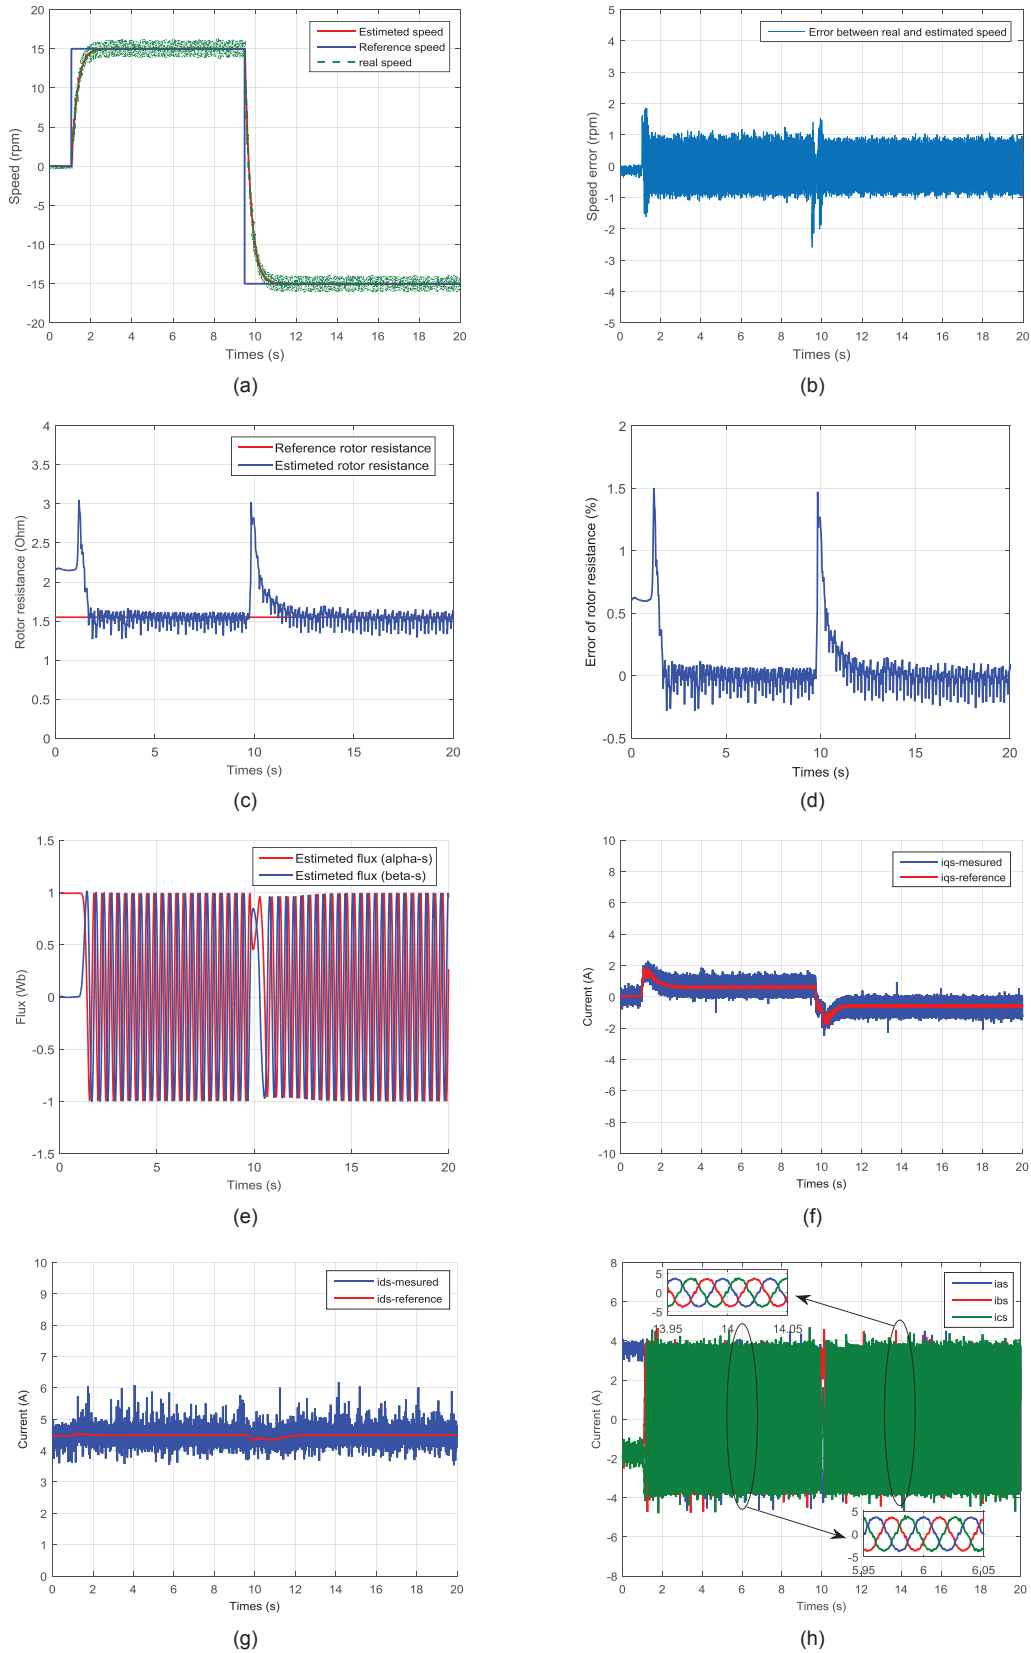

These results confirm that the control scheme, even at low speeds, has a good robustness and a good tracking performance.

## 5. Conclusion

In this paper, a very low rotor speed estimation of the speed sensorless control of the IM with online rotor resistance tuning has been designed. The technique of this simultaneous estimation is based on the MRAS method. The analysed closed-loop stability of the presented method has also been proved though the Lyapunov stability theory. The online rotor resistance estimation scheme has been proposed to be updated in the adjustable model in each computational step, which guarantees the stability of the drive and ensures the accuracy of sensorless speed control. The experimental results show that the rotor resistance is sensitive to the load variation. More importantly, the validity of the proposed sensorless ISFOC of the induction motor drive was proven by experiments for a very

**Fig. 12.** Experimental results of step response (15 rpm) with load torque applied and removed at  $t = 7$  s and  $13$  s, respectively

**Fig. 13.** Experimental results of step response = 15 rpm with inverting direction at the moment  $t = 9.5$  s

low speed. Thus, all experimental results confirm the high dynamic performances of the developed drive system and show the validity of the proposed method.

## Nomenclature

$v_{ds}, v_{qs}, i_{ds}, i_{qs}$	$d, q$ - axis stator voltage and current components
$\phi_{ds}, \phi_{qs}$	$d, q$ - axis stator flux components
$\phi_{\alpha s}, \phi_{\beta s}$	$\alpha, \beta$ - axis stator flux components
$R_r, R_s$	Rotor and stator resistances
$L_r, L_s$	Rotor and stator self-inductances
$M$	Mutual inductance
$n_p$	Number of pole pairs
$\omega_s, \omega$	Synchronous and rotor angular speeds
$\omega_{sl}$	Slip angular speed ( $\omega_s - \omega$ )
$T_e, T_l$	Electromagnetic and load torques
$J$	Moment of inertia
$f$	Friction constant
$\tau_s, \tau_r$	Stator and rotor time constants
$k_{vp}, k_{vp}$	Integral and proportional gains of the IP speed controller
$k_{ip}, k_{ip}$	Integral and proportional gains of the PI current controller
$\sigma$	Total leakage constant
$\hat{\cdot}, *$	Estimated and reference values
$p = \frac{d}{dt}$	Differential operator
