Abstract. In this study, we propose a novel keyed hash algorithm based on a Boolean function and chaotic attractor. The hash algorithm called BentSign is based on two Signature attractors and XOR function and a bent Boolean function. The provided theoretical and experimental results confirm that the novel scheme can generate output hashes with a good level of security, collision resistance, and protection against most common attacks.

Key words: hash algorithm, chaotic attractor, Bent Boolean function, pseudorandom bit generation scheme.

1. Introduction

Keyed hash algorithms play an important role in communication services. They map data of arbitrary lengths to data of fixed length. Applications include message authentication, password storage, and data integrity. The cryptographic hash algorithms were introduced in [8] by Diffie and Hellman for using in public key infrastructure. They are characterized by: (a) sensitivity, (b) collision resistance, (c) uniform distribution, and (d) static confusion and diffusion properties.

In [6, 14, 17, 20, 21, 28–31], and [36], a number of generation schemes and program tools based on chaotic attractors and shift registers, are proposed. They can be successfully integrated in social networks [19] and [37].

In recent years, high dimensional chaotic systems have been admirable scientific area and have got much emphasis in data transmissions field. In [9], an image encryption constructed by eight dimensional chaotic map is proposed. In [39], a video encryption algorithm based on the twelve-dimensional chaotic map and the Ikeda delay differential equation is presented. The authors of [1] used high dimensional map to present novel parallel hash algorithm. A novel hash function based on a four-dimensional hyperchaotic Lorenz system is designed in [22]. Other examples with research about high dimensional chaos based hash algorithms can be found in [10–12, 15], and [38]. The high dimensional chaotic systems have significant characteristics such as difficult dynamic reconstruction, long period without any doubling, and ergodicity [1, 4].

In our humble opinion, the main contributions of our work can be summarized as follows:

- We propose novel pseudorandom bit algorithm based on two Signature attractors, which has good statistical options;
- We combine the pseudorandom generator with bent Boolean function to novel keyed hash algorithm;
- We evaluate the proposed algorithm, and the results illustrate that it has good capabilities of confusion and diffusion, strong collision resistance and has desirable security properties that can withstand most common attack such as birthday attack, meet-in-the-middle attack, and pre-image attack.

In Section 2 we present a novel pseudorandom output bit scheme based on two Signature attractors. In Section 3 we provide some introduction to bent Boolean functions. In Section 4 we present the novel hash algorithm BentSign and complete security analysis is given. Finally, the last section concludes the paper.

2. Pseudorandom bit construction based on chaotic attractor

The work presented in this section was motivated by recent developments in chaos-based pseudorandom generation [13,32–34], and [35].

2.1. Proposed pseudorandom bit generation scheme. The Signature attractor is presented in [26], Eq. (1):

$$\begin{aligned} x_{t+1} &= x_t \cos\theta_t - y_t \sin\theta_t + 1 - 0.8 x_t z_t \,, \\ y_{t+1} &= x_t \sin\theta_t + y_t \cos\theta_t \,, \\ z_{t+2} &= 1.4 z_{t+1} + 0.3 z_t (1 - z_t), \\ \theta_t &= 5.5 - \frac{1}{\sqrt{x_t^2 + y_t^2 + z_t^2}}. \end{aligned} \tag{1}$$

Manuscript submitted 2018-08-25, revised 2018-11-27, initially accepted for publication 2018-12-14, published in June 2019.

With initial values (x_i, y_i), for $i = 150..950$, $x_0 = -0.7390212$, $y_0 = -0.7244441$, $z_0 = 0.3999123$, and $z_1 = 1.454601$, two-dimensional model of Signature attractor is illustrated in Fig. 1, and three-dimensional models viewed from two different angles are plotted in Fig. 2.

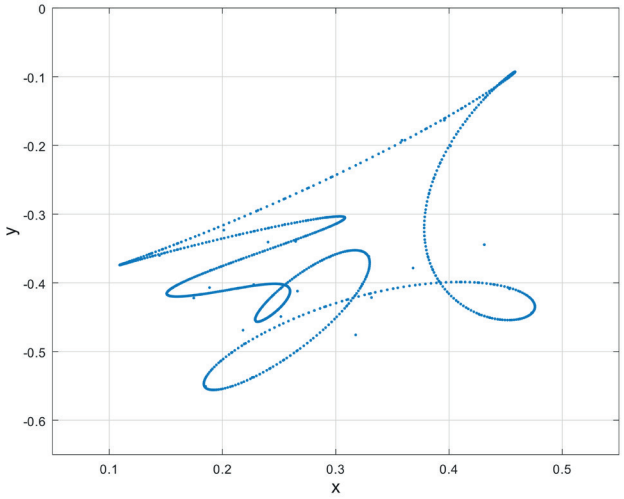

Fig. 1. The two-dimensional plot of Signature attractor of Eq. (1), where $t = 150..950$; $x - y$ plane

The new generator is slightly modified scheme of the algorithm presented in [13]. It is based on the following two Signature attractors:

$$
\begin{aligned}
x_{0,t+1} &= x_{0,t}\cos\theta_{0,t} - y_{0,t}\sin\theta_{0,t} + 1 - 0.8x_{0,t}z_{0,t}\,,\\
y_{0,t+1} &= x_{0,t}\sin\theta_{0,t} + y_{0,t}\cos\theta_{0,t}\,,\\
z_{0,t+2} &= 1.4z_{0,t+1} + 0.3z_{0,t}(1 - z_{0,t})\\
\theta_{0,t} &= 5.5 - \frac{1}{\sqrt{x_{0,t}^2 + y_{0,t}^2 + z_{0,t}^2}}\,,\\
x_{1,t+1} &= x_{1,t}\cos\theta_{1,t} - y_{1,t}\sin\theta_{1,t} + 1 - 0.8x_{1,t}z_{1,t}\,,\\
y_{1,t+1} &= x_{1,t}\sin\theta_{1,t} + y_{1,t}\cos\theta_{1,t}\,,\\
z_{1,t+2} &= 1.4z_{1,t+1} + 0.3z_{1,t}(1 - z_{1,t}),\\
\theta_{1,t} &= 5.5 - \frac{1}{\sqrt{x_{1,t}^2 + y_{1,t}^2 + z_{1,t}^2}}
\end{aligned}
\tag{2}
$$

and is based on the following steps:

1. The elements $x_{0,0}$, $y_{0,0}$, $z_{0,0}$, $z_{0,1}$, $x_{1,0}$, $y_{1,0}$, $z_{1,0}$, and $z_{1,1}$ from Eq. (2) are initialized with values.
2. The attractors from Eq. (2) are iterated for L_0 and L_1 times.
3. The iteration of the Eq. (2) progresses, and we get six real fractions $x_{0,m}$, $y_{0,m}$, $z_{0,m+1}$, $x_{1,n}$, $y_{1,n}$, and $z_{1,n+1}$, which are post-processed as follows:

$$
\begin{aligned}
s_1 &= mod(abs(integer(x_{0,m} \times 10^7)), 2),\\
s_2 &= mod(abs(integer(y_{0,m} \times 10^7)), 2),\\
s_3 &= mod(abs(integer(z_{0,m+1} \times 10^7)), 2),\\
s_4 &= mod(abs(integer(x_{1,n} \times 10^7)), 2),
\end{aligned}
$$

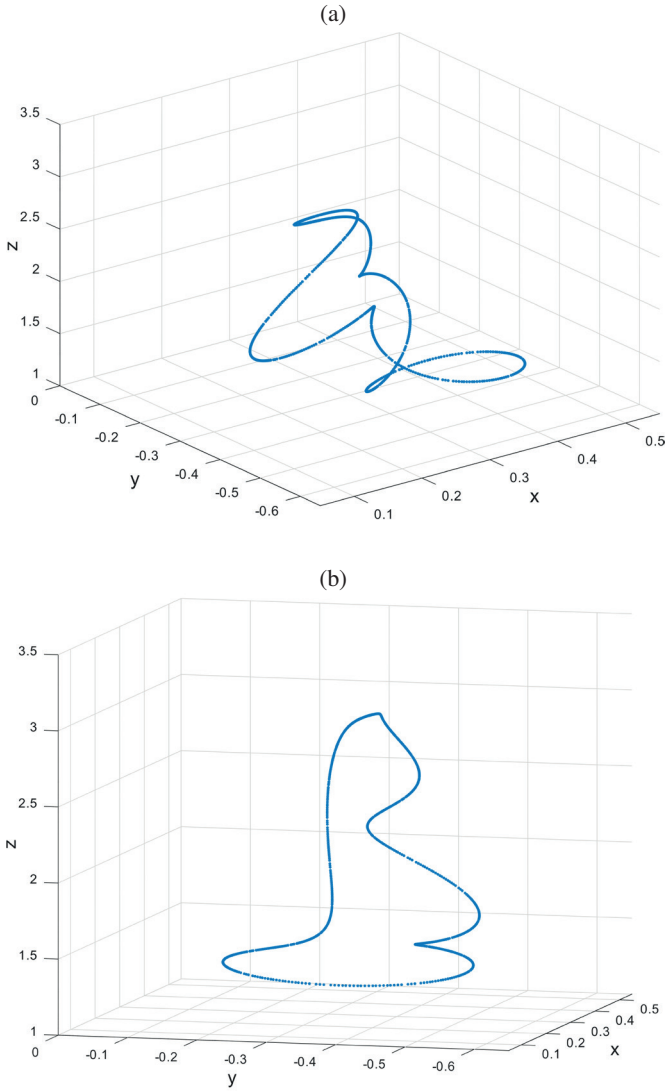

Fig. 2. The three-dimensional plots of Signature attractor of Eq. (1), where $t = 150..950$

$$
\begin{aligned}
s_5 &= mod(abs(integer(y_{1,n} \times 10^7)), 2),\\
s_6 &= mod(abs(integer(z_{1,n+1} \times 10^7)), 2),
\end{aligned}
$$

where $integer(x)$ returns the integer part of x, truncating the value at the decimal point, $abs(x)$ returns the absolute value of x, and $mod(x, y)$ returns the reminder after division.

4. Perform logical XOR between s_1, s_2, s_3, s_4, s_5, and s_6 to get a single output bit.
5. Return to Step 3 until the bit stream limit is reached.

The proposed pseudorandom bit generation scheme is implemented in C++ programming language, using the following initial values: $x_{0,0} = -0.4584282$, $y_{0,0} = -1.7876741$, $z_{0,0} = 0.1964$, $z_{0,1} = 1.020591$, $x_{1,0} = -0.7390212$, $y_{1,0} = -2.7244441$, $z_{1,0} = 0.3999123$, $z_{1,1} = 1.454601$, $L_0 = 714$, and $L_1 = 1278$.

2.2. Key space analysis. The set of all initial values compose the key space. The novel generation scheme has eight input parameters $x_{1,0}$, $y_{1,0}$, $x_{2,0}$, and $y_{2,0}$. According to [42], the com-

putational precision of the 64-bit double-precision number is about 10^{-15}, thus the key set is $(10^{15})^8$ bits, which is more than 2^{398} bits. The novel pseudorandom generator posses a large key space to defend against exhaustive key search attack [2]. Moreover, the initial iteration values L_0 and L_1 can also be used as a part of the key space.

2.3. Statistical tests. In order to measure randomness of the sequences of bits produced by the new pseudorandom number algorithm, we used the statistical applications NIST [5], DIEHARD [16], and ENT [40].

For the NIST suite, we outputted 1000 binary series of length $1,000,000$ bits. The results from the tests are given in Table 1. The minimum pass rate for each statistical test with the exception of the Random excursion (variant) test is approximately 980 for a sample size of 1000 binary sequences. The minimum pass rate for the Random excursion (variant) test is approximately 618 for a sample size of 632 binary sequences. The output bits from the proposed pseudorandom bit generator scheme passed successfully all the NIST tests.

Table 1
NIST test suite results

NIST test	P-value	Pass rate
Frequency (monobit)	0.190654	989/1000
Block-frequency	0.382115	991/1000
Cumulative sums (Forward)	0.095426	988/1000

Serial 2	0.339271	991/1000
Linear complexity	0.100109	989/1000

The DIEHARD application is a set of 19 statistical tests and they return $P-values$, which should be uniform in $[0,1)$, if the input stream contains pseudorandom numbers. The $P-values$ are obtained by $p = F(y)$, where F is the assumed distribution of the sample random variable y, often the normal distribution. BentSign algorithm passed successfully all DIEHARD tests, Table 2.

The ENT software includes following tests: entropy, optimum compression, χ^2 distribution, arithmetic mean value, Monte Carlo value for π, and serial correlation coefficient. Sequences of bytes are stored in files. We tested output series of 125,000,000 bytes of the BentSign. The algorithm passed successfully all ENT test, Table 4, and Table 5, and Table 3.

Table 2
DIEHARD statistical test results

DIEHARD test	P-value
Birthday spacings	0.411472
Overlapping 5-permutation	0.619766
Binary rank (31×31)	0.887539

Table 3
ENT statistical test results

ENT test	Results
Entropy	7.999999 bits per byte
Optimum compression	OC would reduce the size of this 125000000 byte file by 0%
χ^2 distribution	For 125000000 samples is 233.87, and randomly would exceed this value 82.47% of the time
Arithmetic mean value	127.4979 (127.5 = random)
Monte Carlo π estim.	3.141588914 (error 0.00%)
Serial correl. coeff.	0.000111 (totally uncorrelated = 0.0)

Based on the good test results, we can conclude that the novel pseudorandom bit generation algorithm has satisfying statistical properties and provides acceptable level of security.

3. Bent Boolean functions

In this section we refer to works of [7, 23], and [25].

Definition 1. A Boolean function f in n variables is map from $\mathbb{V}_n$ (the vector space on n dimension) to the two-element Galois field $\mathbb{F}_2$. The (0,1)-sequence defined by $(f(\mathbf{x}_0), f(\mathbf{x}_1), \ldots, f(\mathbf{x}_{2^n-1}))$ is called the truth table of f, where $\mathbf{v}_0 = (0,\ldots,0,0)$, $\mathbf{v}_1 = (0,\ldots,0,1)$, $\ldots$, $\mathbf{v}_{2^n-1} = (1,\ldots,1,1)$, lexicographically sorted list.

To each Boolean function $f : \mathbb{V}_n \to \mathbb{F}_n$ we associate *sign* function, denoted by $\hat{f} : \mathbb{V}_n \to \mathbb{R}^* \subseteq \mathbb{C}^*$ and defined by $\hat{f}(\mathbf{x}) = (-1)^{f(\mathbf{x})}$.

Definition 2. The Walsh transform of a function f on $\mathbb{V}_n$ (with the values of f taken to be real numbers 0 and 1) is the map $W(f) : \mathbb{V}_n \to \mathbb{R}$, defined by

$$W(f)(\mathbf{w}) = \sum_{\mathbf{x}\in\mathbb{V}_n} f(\mathbf{x})(-1)^{\mathbf{w}\cdot\mathbf{x}},$$

which defines the coefficients of f with respect to the orthonormal basis of the group characters $Q_{\mathbf{x}}(\mathbf{w}) = (-1)^{\mathbf{w}\cdot\mathbf{x}}$ (where $\mathbf{w}\cdot\mathbf{x}$ is the scalar product); f can be recovered by the inverse Walsh transform

$$f(\mathbf{x}) = 2^{-n} \sum_{\mathbf{w}\in\mathbb{V}_n} W(f)(\mathbf{w})(-1)^{\mathbf{w}\cdot\mathbf{x}}.$$

Definition 3. A Boolean function f in n variables is called *bent* if and only if the Walsh transform coefficients of $\hat{f}$ are all $\pm 2^{n/2}$, that is, $W(\hat{f})^2$ is constant.

Lemma 1. If a bent function f exists, then n must be even, $n = 2k$.

They are designed two classes of bent Boolean functions on $\mathbb{V}_n$, $n = 2k$. The first one is: Let $x_1, y_1, \ldots, x_k, y_k$ be independent variables and let $P(\mathbf{x})$ be an arbitrary polynomial, where $\mathbf{x} = (x_1, \ldots, x_k)$. Then

$$f_1(x_1, y_1, \ldots, x_k, y_k) = \sum_{i=1}^{k} x_i y_i \oplus P(\mathbf{x})$$

is bent function. This generalizes Corollary 2.

Lemma 2. The function

$$f(\mathbf{x}) = x_1 x_2 \oplus \cdots \oplus x_{2k-1} x_{2k},\ k \geq 1, \tag{3}$$

is bent.

4. Hash algorithm based on bent Boolean function and chaotic attractor

In this section, we extend the work of Ref. [38] by combining chaotic attractors with bent Boolean function.

4.1. Proposed Keyed hash algorithm based on bent Boolean function and chaotic attractor. In this subsection, the combination of bent Boolean and Signature attractors is used to design a keyed hash algorithm named BentSign.

Let n be the bit of the final hash value. The parameter n usually supports five bit lengths, 128, 160, 256, 512, and 1024 bits. We consider input message (string) M' with arbitrary length. The proposed hash algorithm BentSign consists of the following steps:

1. The input message M is converted into binary sequence using ASCII table.
2. The binary sequence from Step 1 is padded with a single bit of one followed by bits of zeroes until the M' has length m, obtained as multiple of n.
3. The novel pseudorandom bit generation algorithm (Section 2) based on two Signature attractors and XOR function is repeatedly iterated, getting m bits. m-sized vector P is produced.
4. The m-sized vectors M' and P are united in a new m-sized vector, N, using XOR operation.
5. The vector N is split into p blocks, $N_1, N_2, ..., N_p$, each of length n and $m = np$ is the total length of the vector N.
6. A temporary n-sized vector T is obtained by $T = N_1 \oplus N_2 \oplus \cdots \oplus N_p$.
7. A temporary n-sized vector U is taken and all of its elements are initialized to 0s.
8. The bits from the temporary vector T are processed one by one sequentially. If the current bit t_i is 1 then update $t_i = t_i \oplus s$, where s is the next bit from the novel pseudorandom generator based on two Signature attractors and XOR function (Section 2).
9. The novel pseudorandom bit generation algorithm (Section 2) based on two Signature attractors and XOR function is repeatedly iterated, getting n bits. n-sized vector R is produced.
10. Take the Eq. (3) for $k = 2n$, substitute the odd elements with the bits from vector T and the even elements with the bits from vector R, and calculate the function $f(\mathbf{x})$ to take one single bit u.
11. If the current bit u is 1, the vector U is XOR-ed with the next n bits from the novel pseudorandom generator based on two Signature attractors and XOR function (Section 2). If the current bit u is 0, the matrix U is bitwise rotated left by one bit position.
12. Return to Step 8, until the end of the vector T.
13. The final hash value is obtained by $H = T \oplus U$.

The proposed BentSign hash algorithm is implemented in C++ programming language.

4.2. Distribution analysis. In this subsection, we demonstrate uniformly distributed hash values in the compressed range, when $n = 128$. The input message is taken from Ref. [38]:

Konstantin Preslavsky University of Shumen has inherited a centuries-long educational tradition dating back to the famous Pliska and Preslav Literary School (10th c). Shumen University is one of the five classical public universities in Bulgaria it is recognized as a leading university that offers

modern facilities for education, scientific researches and creative work.

The ASCII code distribution of input message and the corresponding BentSign hexadecimal values are shown in Fig. 3a and 3b. Another input message with the same length but all of blank spaces, is created. The ASCII code distribution of the blank-spaced input message and the corresponding BentSign hexadecimal hash value are shown in Fig. 3c and 3d. The BentSign hash plots, 3b and 3d, are uniformly distributed in compress range even under particularly conditions.

4.3. Sensitivity analysis. To illustrate the sensitivity of BentSign, simulation experiments have been accomplished under the following 10 conditions [38]:

Condition 0: Blank message.

Condition 1: The input string is the same as the one in Section 4.2;

Condition 2: Change the letter *'K'* in the input into *'k'*.

Condition 3: Change the zero in the input to one.

Condition 4: Change the word *'School'* in the input message to *'school'*.

Condition 5: Change the comma *','* in the input string to *'.'*.

Condition 6: Add a blank space at the end of the input string.

Condition 7: Change the word *'recognized'* in the input string to *'recognize'*.

Condition 8: Subtracts 1×10^{-15} from the input value $x_{1,0}$.

Condition 9: Adds 1×10^{-15} to the input key value $y_{2,0}$.

The corresponding 128-bit hash values in hexadecimal number system are the following:

Condition 0: FAA8C89DD3970E19A3856027FFF3ED79

Condition 1: B26D06E24E790A34A26C1C0E07B55313

Condition 2: 79F521281FDB6DBA897CF3D4A12CB701

Condition 3: 30DDCB05DD103FAB7241D2029CAF9A23

Condition 4: 953A4A42777F2CC24301A0CD6A612AA6

Condition 5: A6AB45F273F67861927CADF07041CDF7

Condition 6: D5F9F9836AAFE5F7018EBAF2DA044594

Condition 7: 0758DC3F6022E3881D4EA3A6004E0061

Condition 8: 0FC1618D766D4F7E69A3807A440DE4EE

Condition 9: 3E8BD43EBF8C31EA6FC819D851DCAAC1

The corresponding binary representation of the hash values are illustrated in Figure 4. The values from sensitivity analysis illustrate that the BentSign possesses high sensitivity to any changes in input messages, which make serious differences of output hashes.

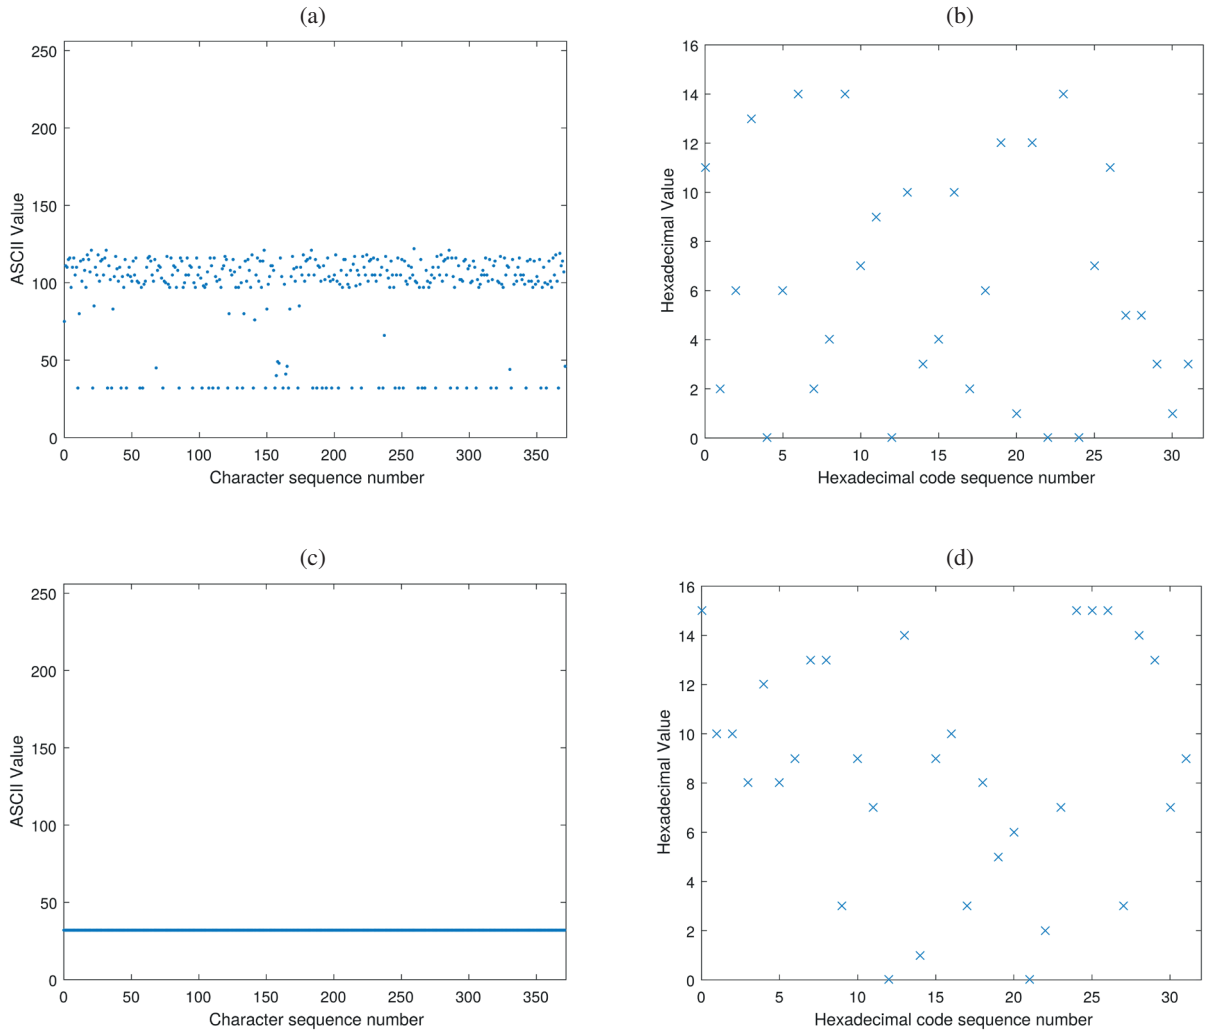

Fig. 3. Distribution of input message and corresponding hash value

Fig. 4. 128-bit hash values of the input messages under ten different conditions: a) Condition 0, b) Condition 1, c) Condition 2, d) Condition 3, e) Condition 4, f) Condition 5, g) Condition 6, h) Condition 7, i) Condition 8, and j) Condition 9

4.4. Statistic analysis of diffusion and confusion Confusion can hide the relationship between the input message and the hash value, and diffusion effect should be that any small changes in the initial data lead to a 50% changing probability of each bit of hash value.

Six functions used here are defined as follows:

Minimum number of changed bits: $B_{\min} = \min\left(\{B_i\}_{i=1}^{N}\right)$;

Maximum number of changed bits: $B_{\max} = \max\left(\{B_i\}_{i=1}^{N}\right)$;

Mean changed bit number: $\bar{B} = \dfrac{1}{N}\sum_{i=1}^{N} B_i$;

Mean changed probability: $P = \dfrac{\bar{B}}{n} \times 100\%$;

Standard deviation of numbers of changed bits:

$$\Delta B = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}(B_i - \bar{B})^2}$$

Standard deviation: $\Delta P = \sqrt{\dfrac{1}{N-1}\sum_{i=1}^{N}\left(\dfrac{B_i}{n} - P\right)^2} \times 100\%$,

where N is the total number of tests and B_i is the number of changed bits in the i-th test (Hamming distance).

Two types of statistical tests are performed [10, 11]: type A and type B. In the type A test, an input string, of size $L = 50n$ is generated and its corresponding $n-$bit hash value is computed. Then, a new string is generated by choosing a single bit at random from the original string and modified to zero if it is one or to one if it is zero. The n-bit hash value of the new string is then compared with that of the original string and the Hamming distance between the two hash values is recorded as B_i. This is then repeated N times, where each time, a new original string is chosen and one of its bits is randomly chosen and modified to zero if it is one or to one if it is zero. Tables 6–10 present results of these tests for $n = 128, 160, 256, 512, 1024$.

In the type B test, the plain data M of size $L = 50n$ bits is generated at random and its corresponding n-bit hash value is computed. Then, a single bit of the plain data is chosen, modified to zero if it is one or to one if it is zero, and the hash value of the modified data is calculated. The two hash values are compared, and the number of changed bits is calculated and recorded as B_i. The same original string is used for all N iterations.

In Fig. 5, the Hamming distance obtained from test type A with $n = 128$ and $N = 10000$ is shown.

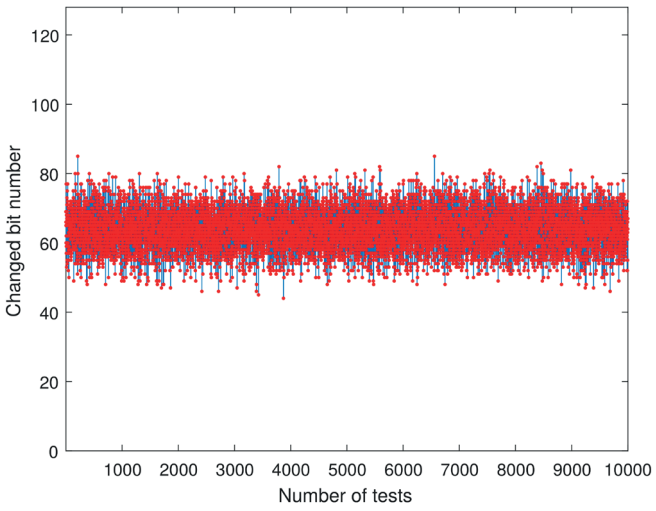

Fig. 5. Distribution of the Bi values obtained in a type A test with $n = 128$ and $N = 10000$

Tables 12–16 list the results obtained in tests of type B for $n = 128, 160, 256, 512, 1024$, and various values of N.

Comparing the results with three chaos based hash algorithms given in Table 17, the BentSign has analogous values.

In Tables 6–16 we can see that both types of tests, the mean changed bit number $\bar{B}$ and the mean probability P are very close to the ideal values $n/2$ and 50%. These results illustrate that the BentSign algorithm has strong capacity against confusion and diffusion attacks.

4.5. Collision analysis. A general feature of a hash algorithm is to possess collision resistance capability, the following two types of tests are performed, type A and type B [10]. In tests of type A, an original string of size $L = 50n$ is generated and its corresponding n-bit hash code is calculated and stored in ASCII format. Then, a new string is generated by choosing a single bit at random from the input string and modified to zero if it is one or to one if it is zero. The n-bit hash code of the new string is calculated and stored in ASCII format. The two hash codes are compared, and the number of ASCII symbols with the same value at the same location is counted. Moreover, the absolute difference D between the two hash codes is calculated by the following formula $D = \sum_{i=1}^{n/8} \left| decimal(e_i) - decimal(e_i') \right|$, where e_i and e_i' be the i-th entry of the input and new hash value, respectively, and function $decimal(\,)$ converts the entries to their equivalent decimal values. The test of type A is repeated $N = 10,000$ times, and experimental minimum, maximum, and mean of D are presented in Table 18 for different hash values of size $n = 128$, 160, 256, and 512.

Table 18
Absolute difference D for hash values generated under tests of type A, where $N = 10,000$

n	Maximum	Minimum	Mean
128	2450	573	1362
160	2744	791	1709
256	4007	1543	2731
512	7275	3712	5459

Table 19 shows the absolute differences of 128-hash codes generated under tests of type A, where $N = 10,000$, and related hash algorithms. The results illustrate that BentSign has comparable values.

Table 19
Comparison of the absolute difference for 128-hash values generated under tests of type A, where $N = 10,000$

n	Maximum	Minimum	Mean
BentSign	2450	573	1362
Ref. [10]	2391	656	1364
Ref. [38]	2386	537	1367
Ref. [41]	2064	655	1367

The count of locations where the ASCII characters are equal, where $N = 10,000$ and the hash codes are calculated under tests of type A, is presented in Table 20 and distributions of the 128-hash and 160-hash values, are illustrated in Figure 6 and Figure 7.

Table 20
Count of positions in Collision test for $N = 10,000$, generated under tests of type A

n	0	1	2	3	4	5
128	9373	607	20	0	0	0
160	9290	688	21	1	0	0
256	8809	1126	60	4	1	0
512	7782	1949	251	17	1	0

In the type B tests, an input message M of a fixed size $L = 50n$ bits is created at random and its corresponding n-bit input hash

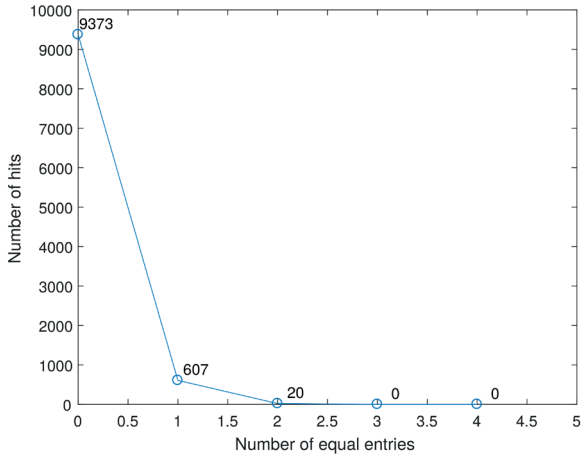

Fig. 6. Distribution of the number of locations where the ASCII symbols are equal in the 128-bit hash values generated under tests of type A, where $N = 10,000$

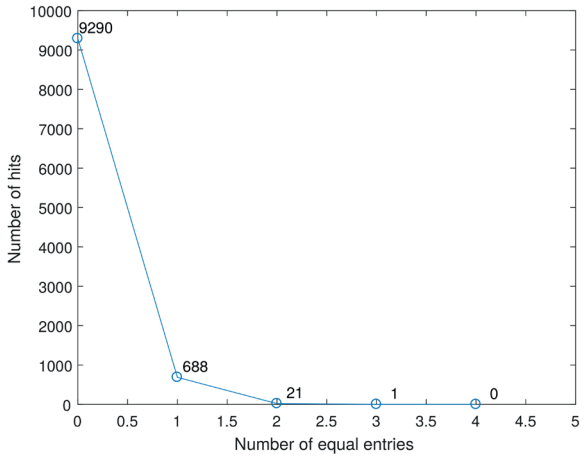

Fig. 7. Distribution of the number of locations where the ASCII symbols are equal in the 160-bit hash values generated under tests of type A, where $N = 10,000$

value is computed. Then, a single bit of the input message is chosen, modified to 0 if it is 1 or to 1 if it is 0, and the hash value of the modified message is calculated. Table 21 presents minimum, maximum, and mean values of D for different hash values of size $n = 128$, 160, 256, and 512 generated under tests of type B. The same input message is used for all N iterations. Comparison with other algorithm is presented in Table 22.

Table 21
Absolute difference D for hash values generated under tests of type B, where $N = 50n$

n	Maximum	Minimum	Mean	N
128	2225	658	1382	6400
160	2533	886	1677	8000
256	4132	1871	2953	12800
512	7224	3687	5345	25600

Table 22
Comparison of absolute difference D for 128-hash values generated under tests of type B, where $N = 6400$

n	Maximum	Minimum	Mean
BentSign	2225	658	1382
Ref. [10]	2421	735	1576
Ref. [11]	2294	661	1360
Ref. [38]	2035	636	1248

In addition to the above experiments, the tests of type B are repeated for very short input data consisting of a single $n-bit$ block, Table 23. The count of positions where the ASCII symbols are equal, generated under tests of type B, is listed in Table 24 and distribution of 160-hash values and $N = 8000$, is illustrated in Figure 8.

Table 23
Absolute difference D for hash values generated under tests of type B, where $N = n$

n	Maximum	Minimum	Mean	N
128	1983	942	1456	128
160	2409	1301	1802	160
256	3821	2327	2977	256
512	6699	4125	5306	512

Table 24
Count of positions in Collision test, generated under tests of type B

n	N	0	1	2	3
128	128	128	0	0	0
128	6400	6021	356	23	0
160	8000	7497	489	14	0
256	12800	11460	1286	54	0

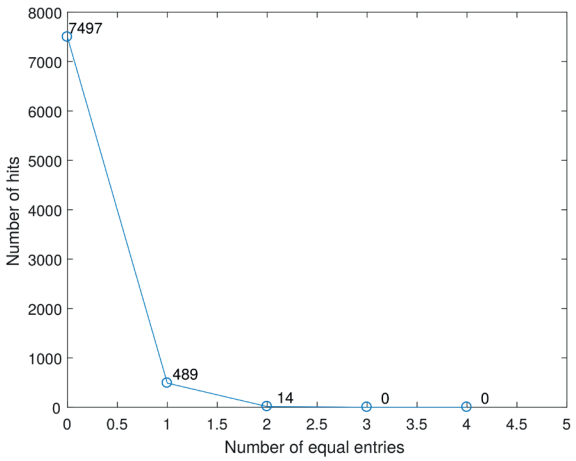

Fig. 8. Distribution of the number of locations where the ASCII symbols are equal in the 160-bit hash values generated under tests of type B, where $N = 8000$

The empirical values confirm that the novel hash algorithm BentSign has an excellent collision resistance.

4.6. Birthday attack analysis. The birthday attack is one of the typical attack on the hash algorithms. The primary target of this attack is to find two input messages with identical hash values [18, 27], and [41]. The time complexity of the attack is $O(2^{n/2})$. Thus for the minimal 128-bit hash value, the attack needs to have 2^{64} attempts, which is sufficient to make the birthday attack unrealistic.

4.7. Meet-in-the-middle attack analysis. The meet-in-the-middle attack attempts to find collisions on intermediate hash values [18]. In the BentSign, the intermediate results are based on the dynamical values of the chaotic attractor. It means that any small differences in the initial values contributes significant changes in the next-state values [24, 27]. As a result, the proposed hash algorithm can prevent meet-in-the-middle attack.

4.8. Second pre-image attack analysis. For any input message M_1, the second pre-image attack tries to find another input message M_2, that has the same hash value [3, 22]. In the proposed hash algorithm, the calculations are based on the mix of the highly nonlinear Boolean function and chaotic values of the Signature attractor. Thus, the BentSign is protected against second pre-image attack.

5. Conclusions

In this paper, we propose a novel keyed hash algorithm based on a Boolean function and a chaotic attractor. The hash algorithm called BentSign is based on classical bent Boolean function and two Signature attractors. The provided theoretical and experimental results verify that the proposed hash algorithm can generate output hash values with a good level of security, strong collision resistance, and protection against most common attacks.
