## Tasks of data refreshment in information systems

### Abstract

In this work is resolved task of monitoring of databases, functioning for a long period of time and serving the end users. Data of such databases are characterized by a number of parameters one of which is their actuality. For example, collection of outdated data leads to overload of databases. So, such data need to be removed from the databases. In this work is resolved the task of detection of various parameters of data and conditions, determining necessity of their removal from the databases. Due to this, during the long term use of the databases, the last ones will be automatically cleaned up from outdated data preventing the database from overload.

**Keywords:** refreshment, information systems, social tasks, information image, utilization parameter, interpretational descriptions, refreshment measure.

### 1. Introduction

Widespread usage of distributed information systems, oriented on solving social tasks (*SIS*), allows to substantially raise effectiveness of functioning of the social environment. An example of these *SIS* can be systems of social insurance, related to medical services, pension system services and other kinds of services [1]. Basic features of such systems are as follows:

- service life of these systems is rather long,
- information containing in different *SIS* can have common fragments,
- full replacement of a system with another one due to obsolescence is not desirable,
- changes in social information systems have to reflect the corresponding changes in the social environment,
- the possibility to transfer of information fragments from active state to passive state is a natural functioning process of random social systems.

Because an information fragment by itself is an abstraction to a degree, we will discuss not the information fragments but the fragments of information images or the information images as a whole ( $Io_i$ ). Let us review the definition of an information image.

*Definition 1.* An information image is a set of data that has an individual interpretation in the corresponding subject area, which is formally described by the following relation:

$$Io_i(D) = j(x_{i1}, \dots, x_{in}),$$

where  $D$  are data that make up  $Io_i$  and  $x_{ij}$  is an element of the interpretational description of  $Io_i$ .

In most cases  $x_{ij}$  can be a single word or a phrase in the native language of a *SIS* user. Information images  $Io_i$  can have their own structure. This structure describes the interconnection between components  $io_i \in Io_i(D)$ . Description of these interconnections can look like certain functions or another form of description of interconnections between  $io_i(d_i)$  and  $io_j(d_j)$ . This structure corresponds to the description structure of the interpretation  $j(x_{i1}, \dots, x_{in})$  of the information image  $Io_i(D_i)$ . A socially oriented base has to be filled with information images because these images describe different people or single groups from the social environment. Thus, certain data are interconnected corresponding to the description of interpretational extensions  $j(x_{i1}, \dots, x_{in})$ . Features of an information description are mostly determined by specifics of perception of the corresponding image by the users. This perception is met by a hierarchic structure of the corresponding image. A hierarchic structure is formally described by the following relation:

$$Io_i(D_i) = \{(io_{i1}(d_{i1}) \rightarrow io_{i2}(d_{i2}) \rightarrow \dots \rightarrow io_{ik}(d_{ik})) \vee (io_{i2}(d_{i2}) \rightarrow io_{i23}(d_{i23}) \rightarrow io_{i24}(d_{i24}) \rightarrow \dots \rightarrow io_{i2k}(d_{i2k})) \vee \dots \vee (io_{im}(d_{im}) \rightarrow \dots \rightarrow io_{irg}(d_{irg}))\}, \quad (1)$$

where the indexes  $(i, m, k, \dots, n)$  define the placement of a fragment  $io_{i,m,k,\dots,n}(d_{i,m,k,\dots,n}) \in Io_i(D_i)$  in the hierarchic structure  $S[Io_i(D_i)]$ .

### 2. Basic concepts

To choose information fragments for their exclusion from the active part of *SIS* or for utilization of non-active  $Io_i(D_i)$ , the corresponding choice parameters are used, which will be called utilization parameters ( $P_u^i$ ). These parameters are formed within the system (*SUD*) that processes the utilization  $Io_i(D_i)$ . Defining of these parameters is based on using the following conditions and data:

- maximum time period when the chosen  $Io_i(D_i)$  is non-active, ( $P_u^t$ ),
- if the data received by user corresponding with his request do not meet his expectations, ( $P_u^M$ ),
- the data which, when used within the scope of tasks being solved, lead to occurrence of structural anomalies in this system, ( $P_u^S$ ),
- the data which are no more relevant, which can happen in the social environment due to changes occurring in it, ( $P_u^A$ ).

The mentioned conditions can be extended by others, that reflect certain features or specifics of each single system [2, 3]. On the basis of these conditions the *SUD* system forms a system of utilization parameters. Thus, the main task that needs to be solved, is to define the utilization parameters, used to define data characterized the above-mentioned conditions and thus require utilization. As a whole, the process of defining utilization parameters and removing the corresponding  $Io_i(D_i)$  or their replacement with the corresponding up-to-date  $Io_i(D_i)$  is called refreshment of *SIS*.

Utilization of  $Io_i(D_i)$  in the system consists of the following transformations, conducted by *SUD* in the *SIS* system:

- certain  $Io_i(D_i)$  or their fragments are transferred from the *SIS* into the data archiving system (*SAD*),
- a necessary modification of  $Io_i(D_i)$  is conducted, the original of the modified image is transferred from the *SIS* into the data archiving system (*SAD*),
- in the *SIS*, one information image  $Io_i(D_i)$  is replaced with another information image  $Io_i^*(D_i)$ , however, the original of the replaced image is transferred from the *SIS* into the data archiving system (*SAD*),
- additional  $Io_{ij}(D_{ij})$ , absent in the *SIS* before, is introduced into the *SIS*,
- additional authentication of  $Io_i(D_i)$  is performed, because *SUD* has detected absence in the  $Io_i(D_i)$  the necessary fragments of interpretation description of  $Io_i(D_i)$  in the subject area of interpretation of *SIS*.

The *SUD* system cooperates with *SIS* in the following ways [4]:

- by performing control of all  $Io_i(D_i)$  corresponding to the formed strategy of data check of the *SIS* system,
- by performing analysis of a dialog implemented between the *SIS* and the user or the system that uses *SIS*,
- by implementing analysis of *SIS* functioning, performed on the basis of data regarding the requirements of the owner of *SIS*.

### 3. Solving the main task

Interpretation of different types of utilization parameters  $P_u^i$  and information images  $Io_i(D_i)$  describes why the corresponding

information image is not suitable or not necessary for solving tasks ( $Zd_i$ ) that  $SIS$  is oriented to, which will be called regular tasks ( $Zd_i^S$ ). This means that different types of parameters  $P_u^i$  are quite closely related to the different tasks like  $Zd_i^S$ . For instance, the task of long-term storage of  $Io_i(D_i)$  is typical for information systems like archives and is not a regular task  $Zd_i^S$  for systems like  $SIS$  [5, 6].

One of the utilization parameters is defined by the time interval  $\Delta t_i$ , during which a certain  $Io_i(D_i)$  is not used or is not active. The corresponding utilization parameter will be written as  $P_u^i(\Delta t)$ , where  $\Delta t$  is a parameter argument that defines the value of time interval after which the corresponding  $Io_i(D_i)$  can be considered non-active, which can be described by the following relation:

$$\{\{P_u^i(\Delta t) > \Delta T_i[Io_i(D_i)]\} \& \{Zd_i^h \notin Zd_i^S\}\} \rightarrow \{P_u^i(Io_i(D_i)) \rightarrow (SIS \setminus Io_i(D_i))\}, \quad (2)$$

where  $\Delta T_i$  is a time interval during which  $Io_i(D_i)$  has to be activated,  $Zd_i^h$  is the task of storing  $Io_i(D_i)$  during the time interval of undefined value at the moment of using  $SUD$  system,  $P_u^i(SIS)$  is a set of utilization parameters of the  $SIS$  system. The value of  $\Delta t$  for each single  $Io_i(D_i)$  can be individual. Thus, within the scope of the work of  $SUD$  system the value of  $\Delta T_i$  can be chosen as the maximum of all  $\Delta T_i$  values of different  $Io_i(D_i) \in SIS$ .

Utilization parameters  $P_u^i$ , as well as the  $SIS$  system itself, are closely related to the subject area of interpretation of information images of the system, which will be written as  $W_i(SIS_i)$ .

A condition that defines the next  $P_u^i$  parameter describes the situation when the user or another system, while using  $Io_i(D_i)$  from the  $SIS_i$ , could not solve the task because of inconsistency of the received image with the expected data. All tasks that can use  $Io_i(D_i)$  from the  $SIS_i$  are basically tasks related to  $Zd_i^S \in SIS_i$ . The description of  $Zd_i^S$  present in the  $SIS_i$  contains the description of all requirements to  $Io_i(D_i)$ . In this case, the following situations are possible:

- the user of  $Io_i(D_i)$  misuses  $Io_i(D_i)$ ,
- the  $Zd_{ij}^K$  task description used by the user does not comply with the  $Zd_i^S$  task description from the  $SIS_i$ .

In the first case  $J(Io_{ij})[Zd_{ij}^K] \neq J(Io_{ij})[Zd_{ij}^S]$ , and the system refuses to service the user. In the second case  $J(Io_{ij})[Zd_{ij}^K] \not\Leftarrow J(Io_{ij})[Zd_{ij}^S]$ , which means the  $J(Io_{ij})$  contains inconsistency with  $J[W_i(SIS_i)]$ . The  $SUD$  system performs analysis of the mentioned inequality in order to determine whether  $Zd_{ij}^K$  is not correct or  $Zd_{ij}^S \Leftarrow W_i(SIS_i)$ , which corresponds to the situation when  $J(Io_{ij})[Zd_{ij}^S] \Leftarrow W_i(SIS_i)$ . This means that there were changes in  $W_i(SIS_i)$  which did not have any representation in  $J(Io_{ij})[Zd_{ij}^S]$  and in the  $SIS_i$  in general. In this case the parameter  $P_u^i \rightarrow P_u^M$ , which corresponds to the situation when  $SIS_i$  is not utilized, but refreshed.

Let us examine the statement:

*Statement 1.* If  $J(Io_{ij})[Zd_{ij}^K] \Leftarrow J(Io_{ij})[Zd_{ij}^S]$ , then there is such a modification  $J(Io_{ij})[Zd_{ij}^S]$ , which will lead to

$$J(Io_{ij})[Zd_{ij}^K] = J^*(Io_{ij})[Zd_{ij}^S].$$

Interpretational descriptions  $J(Io_{ij})=j(x_{i1}^O * \dots * x_{im}^O)$  and  $J(W_i) = j(x_{i1}^W * \dots * x_{in}^W)$  are normalized texts on the native language of the user, and their fragments are written as  $tm_i$ . According to [7], there is a full output system for these texts, that consists of the rules of replacement, exclusion, inclusion and transpositions, that, correspondingly, are described by the relations:

$$(tm_{i1} * \dots * tm_{ij} * \dots * tm_{in}) / (tm_{ij} \rightarrow tm_{ik}) \Rightarrow (tm_{i1} * \dots * tm_{ij-1} * tm_{ik} * tm_{ij+1} * \dots * tm_{in}), (tm_{i1} * \dots * tm_{ij} * \dots * tm_{in}) / (tm_{ij} \rightarrow 0) \Rightarrow (tm_{i1} * \dots * tm_{i(j-1)} * tm_{i(j+1)} * \dots * tm_{in}), (tm_{i1} * \dots * tm_{ij} * \dots * tm_{in}) / (tm_{ij}(+)tm_{ir}) \Rightarrow (tm_{i1} * \dots * tm_{ij} * \dots * tm_{ir} * \dots * tm_{in}), (tm_{i1} * \dots * tm_{ij} * \dots * tm_{in}) / (tm_{ij} * \dots * tm_{in}) \Rightarrow (tm_{i1} * \dots * tm_{ij} * \dots * tm_{in}), (tm_{i1} * \dots * tm_{ij} * \dots * tm_{in}) / (tm_{i1} * \dots * tm_{ij} * \dots * tm_{in}) \Rightarrow (tm_{i1} * \dots * tm_{ij} * \dots * tm_{in}), (tm_{i1} * \dots * tm_{ij} * \dots * tm_{in}) / (tm_{i1} * \dots * tm_{ij} * \dots * tm_{in}) \Rightarrow (tm_{i1} * \dots * tm_{ij} * \dots * tm_{in}).$$

$$\dots * tm_{ij} * tm_{ir} * tm_{ij+1} * \dots * tm_{in}), (tm_{i1} * \dots * tm_{ij} * \dots * tm_{in}) / (tm_{ij} \rightarrow tm_{ij-1}) \Rightarrow (tm_{i1} * \dots * tm_{ij-2} * tm_{ij} * tm_{i(j-1)} * tm_{ij+1} * \dots * tm_{in}).$$

Because the given system is full, it is possible to perform a random transformation  $J(Io_i) \rightarrow J^*(Io_i)$  on its basis, using the following:

$$J(Io_{ij})=j(x_{i1}^O * \dots * x_{im}^O) \text{ and } J(W_i) = j(x_{i1}^W * \dots * x_{in}^W).$$

The condition that defines the parameter  $P_u^M$  is formally described by the relation:

$$\{\{h^K(Io_i(SIS_i)) \rightarrow (SIS_i \rightarrow h^K(Io_i))\} \& \{Io_i^* \neq Io_i\}\} \rightarrow \{P_u^M[Io_i \& W_i(SIS_i)] \rightarrow h^K(Io_i^*)\} \quad (3)$$

The next parameter of the class  $P_u^i$  corresponds to the case when within the  $SIS_i$  such situations occur when certain  $Io_i$  are no longer relevant to  $W_i(SIS_i)$ . This happens because in the  $W_i$ , which is a certain fragment of the social environment, there are natural changes that may miss the  $SIS_i$ . It is obvious that such a situation can be detected in case when user addresses the  $SIS_i$  and the received  $Io_i$  does not allow him to solve his task. Naturally, such situations should be avoided. Because of that, within the  $SIS_i$ , among all the tasks  $Zd_{ij}^S \subset SIS_i$  those are preferred which check and replace or modify the  $Io_i$  with the purpose of ensuring their relevance to  $W_i$ . The parameter which corresponds to this case will be called relevance parameter and written as  $P_u^A$ .

Unlike  $P_u^M$ , the  $P_u^A$  parameter is oriented towards the part of tasks from the task set  $Zd_i^S$ , that are not activated by users addressing the  $SIS_i$ . This part of tasks will be written as  $Zd_{ij}^{SV}$  or the inner regular tasks of the  $SIS_i$ . A possible example of  $Zd_{ij}^{SV}$  is a task of the system audit [8, 9]. Any  $SIS_i$  contains not only data from the subject area of interpretation  $W_i(SIS_i)$ , but also the housekeeping data, that basically, too, are information images that will be written as  $Is_i$ . These  $Is_i$  are in fact characteristics of  $Io_i$  classes. Possible examples of  $Is_i$  are:

- number of addressing a certain class  $Io_i$  by users,
  - duration of  $Io_i$  inactivity,
  - sizes of different  $Io_i$  classes and so on.
- These characteristics are defined by the specifics of  $W_i(SIS_i)$ . Housekeeping data are parameters used to solve tasks like  $Zd_{ij}^{SV}$ . Activation of tasks of  $Zd_{ij}^{SV}$  type is based on the set of criteria related to the housekeeping characteristics. Possible examples of these criteria are:
- intensity of using a certain  $Io_i$  type,
  - sizes of  $Io_i$  of different types,
  - number of denials of service by various  $Io_i$  types,
  - violations of conditions of providing services by the system and so on.

Tasks  $Zd_{ij}^S$  are activated corresponding to the requirements for technical maintenance of the  $SIS_i$ . However, situations can occur when, while the system is servicing the users, anomalies appear. These anomalies, as stated before, are identified by the parameter  $P_u^A$  and are connected with changes in the  $W_i(SIS_i)$ . Any changes in the  $W_i$  performed by workers of the corresponding departments have to be recorded in the corresponding  $SIS_i$ . Because there is no physical connection between the documents, produced in the institutions, and  $Io_i \in SIS_i$ , it is necessary to define certain parameters of  $Io_i$  image from the document and image  $Io_i \in SIS_i$ , which, regardless of the text semantics, would allow to identify the version of the  $Io_i$  text contained in the  $SIS_i$ . Let us assume the following propositions:

*Proposition 1.* Each producer of a new version of an element  $Io_i^*$  has to represent it in such a way that  $Io_i^*$  could be distinguished from  $Io_i$  on the basis of different values of technical parameters.

*Proposition 2.* A relevant image of  $Io_i^*$  is an image, formed on the basis of the document created after the occurrence of  $Io_i \in SIS_i$ .

According to this proposition, if  $Io_i^*(p_{i1}^*, \dots, p_{ik}^*) \neq Io_i(p_{i1}, \dots, p_{ik})$ , a replacement is made:  $Io_i(p_{i1}, \dots, p_{ik}) \rightarrow Io_i^*(p_{i1}^*, \dots, p_{ik}^*)$ . Utilization parameters are used to detect  $Io_i$  that needs to be replaced. Thus,  $P_u^A$  characterizes the difference between  $p_{ij}$  and  $ip_{ij}^*$ , which is described by the relation:

$$\{\forall(p_{ij} \in Io_i) \forall(p_{ij} \in Io_i^*) \exists p_{ik} [p_{ik}^* \neq p_{ij}] \} \rightarrow P_u^A [(Io_i^*(p_{ik}^*) \rightarrow Io_i(p_{ik}))]. \quad (4)$$

Possible examples of  $p_{ij}$  parameters of  $Io_i$  image are image sizes, image structure, coordinates of  $Io_i$  placement in the  $SIS_i$  and others, formed on the basis of  $Io_i$  interpretation in the  $W_i$ .

The utilization parameter, used in the case when anomalies in the  $SIS_i$  appear on the structural level, is written as  $P_u^S$ . This parameter concerns the consistency measure  $\mu(Io_i, Io_j)$  between certain  $Io_i$  and  $Io_j$  in the  $SIS_i$ . If the user chooses  $Io_i$  and  $Io_j$  within a single request, then the number of requests of various users, who choose images  $Io_i$  and  $Io_j$  within a single addressing, defines their consistency measure. Obviously,  $\mu(Io_i, Io_j)$  depends on the structure  $S(SIS_i)$  because the latter considers interconnections between the corresponding  $Io_i$  and  $Io_j$ . However,  $S(SIS_i)$  is formed during the design of  $SIS_i$ , and after a certain amount of time the corresponding, structurally close, images can become weakly dependent, which leads to decrease of  $\mu(Io_i, Io_j)$ . This is defined by the external factors, which are user requests for data in the  $SIS_i$ , and it can be changed during the process of  $SIS_i$  functioning. Change in consistency measure during the  $SIS_i$  functioning between single  $Io_i, Io_j$  must not exceed the given value. If  $\delta\mu(Io_i, Io_j) > \Delta\mu(SIS_i)$ , the system requires structural refreshment. In practice, this could mean that  $SUD$  performs transpositions in the  $S(SIS_i)$  of those images  $Io_i$  that, corresponding to the structure, became inconsistent with the adjacent images  $Io_j$  by the value exceeding  $\Delta\mu(SIS_i)$ . This parameter is formally described by the following relation:

$$\begin{aligned} & \{[\mu t_k(Io_{ij}, Io_{i(j+1)}) = \alpha\mu] \& [\mu t_{k+1}(Io_{ij}, Io_{i(j+1)}) = \beta\mu] \& \\ & \& [(\alpha\mu - \beta\mu) > \Delta\mu] \& \exists Io_{ir} [\mu t_{k+1}(Io_{ij}, Io_{ir}) < \Delta\mu] \& \\ & (Io_{ij} \rightarrow Io_{ir}) \} \rightarrow P_u^S [(Io_{i(j+1)} \rightarrow Io_{ir}) \& (Io_{ir} \rightarrow Io_{i(j+1)})] \end{aligned} \quad (5)$$

When using the introduced utilization parameters, a task arises of defining the fullness of these parameters. This means that it is necessary to determine if these parameters are sufficient to perform the given measure of refreshment of the system  $SIS_i$  [10]. To solve this task it is necessary to prove that the parameter system  $\{P_u^t, P_u^M, P_u^S, P_u^A\}$  is full. Thus, let us define the concept of refreshment measure  $\eta$  of the system  $SIS_i$ . We will introduce the definition:

**Definition 2.** A given refreshment measure  $\eta$  of the system  $SIS_i$  is determined by a certain value of deviation of an integral parameter, that characterizes accordance of the  $SIS_i$  functioning process to the technical requirements, from the real value of this parameter, that characterizes current abilities of  $SIS_i$ .

The mentioned definition of  $\eta$  is in fact similar to the classical definition of reliability of a technical system [11]. Unlike reliability, refreshability defines by which utilization parameters  $P_u^t$  and to what extent we need to perform the system refreshment. Reliability, in its classical sense, means the measure of probability of a system malfunction, because in most cases, to define reliability, data regarding probability of failure of various system elements are used.

Let us assume that an integral parameter  $\mathcal{P}$  is a certain function of single parameters, that, in a sense, can be called technological, which is written in this way:  $\mathcal{P} = F(P_u^t, P_u^M, P_u^S, P_u^A)$ . Then the refreshability measure will be written as:  $\eta = \mathcal{P}_p - \mathcal{P}_i$ , where  $\mathcal{P}_p, \mathcal{P}_i$  are the value of the integral parameter after finishing all stages of  $SIS_i$  design and its current value. As an approximation of explicit form of the  $F$  function, the following linear polynomial will be assumed:

$$\mathcal{P} = \alpha_1^u P_u^t + \alpha_2^u P_u^M + \alpha_3^u P_u^S + \alpha_4^u P_u^A.$$

Thanks to using the data utilization parameters, it is possible to discuss detected deviations of these parameters from the given values and the influence measure of each parameter on the value of system refreshability. In this case it is not necessary to wait for manifestation of change of even one utilization parameter, which in fact represents the system state relatively to this parameter, because  $SUD$  system checks their values corresponding to the refreshing strategy of  $SIS_i$  [12].

Interpretation of situations that correspond to presence of certain values of utilization parameters, is as follows:

- irrelevance of necessary data means that the user receives data and discovers their irrelevance after an attempt to use them by a third party, which in most cases is another information system,
- necessary data do not meet the user expectations, which is discovered by the user, so it is known where the discrepancy is,
- some data, received by user as a set after a single request, are not sufficiently related to each other, which means that they are not placed properly in the  $SIS_i$  structure relatively to their actual importance,
- data are not used during a set time interval, so they are defined as irrelevant for the user.

In this case, the users are divided into the following categories:

- users that address  $SIS_i$  to obtain information from the system, ( $h^K$ )
- users that enter data into the system corresponding to their authority, ( $h^V$ )
- users that maintain the functioning process of the system ( $h^S$ ).

Let us examine the following statement:

**Statement 2.** The system of utilization parameters is full.

This statement means that the system  $\mathcal{P}(SIS_i)$  is full when a random possible user successfully performs requests, that meet the technical requirements, to the system  $SIS_i$ , provided that the values of the utilization parameters are within acceptable range.

Let us assume that  $h^K$  addresses  $SIS_i$ , or  $h^K \rightarrow SIS_i$ . As a result,  $SIS_i$  gives an information image  $Io_i(D)$ , which can be written as the following relation:  $h^K \rightarrow SIS_i \rightarrow Io_i(D) \rightarrow h^K$ . In this case, the following negative situations can take place:

1.  $Io_i(D)$  does not correspond to  $h^K(Io_i^*(D))$ , where  $Io_i^*(D)$  is an image expected by  $h^K$ , or  $h^K \rightarrow SIS_i \rightarrow \neg Io_i^*(D)$ .
2. Using  $Io_i(D)$  has led to a conflict between  $h^K$  and  $St_i$ , or  $h^K(Io_i(D)) \rightarrow \neg(St_i, Io_i)$ .
3. Received images  $(Io_i, Io_j) \rightarrow \neg(Io_i \sim Io_j)$ .
4. A received image  $Io_i(D) \rightarrow \neg(Io_i(D) \& W_i(SIS_i))$ .

If the system  $SIS_i$  is addressed by the user  $h^V$ , the following negative situations can take place:

1. The user  $h^V$  enters an information image into the  $SIS_i$ , which is described by the relation:

$$[h^V(Io_i(D)) \rightarrow (SIS_i)] \rightarrow \{[Io_i(D) \notin W_i(SIS_i)] \& [Io_i(D) \cup SIS_i]\}.$$

2. The user  $h^V$  extracts an information image from the  $SIS_i$ , which is described by the relation:

$$[h^V(Io_i(D)) \rightarrow (SIS_i) \setminus Io_i(D)] \rightarrow \{[Io_i(D) \notin (SIS_i)] \vee \neg Io_i(D)\}.$$

The result of  $h^V$  user actions corresponding to point 1 can lead to the change of  $P_u^A$  value, because  $Io_i(D)$  is incompatible with  $W_i(SIS_i)$ . The result of  $h^V$  user actions corresponding to point 2 can lead to the change of  $P_u^M$  value, because  $Io_i(D)$  is compatible with  $W_i(SIS_i)$  but excessive for  $SIS_i$  and thus is excluded from  $SIS_i$ , however, it can be extracted from  $W_i$  and  $SIS_i$ .

The first case that concerns the  $h^K$  user corresponds to solving within the  $SIS_i$  one of  $Zd_i^S$  tasks and is described by the relation (3).

This means that the following takes place:

$$\{h^K \rightarrow SIS_i \rightarrow \neg(Io_i^*(D))\} \rightarrow \{(SIS_i \rightarrow Io_i) \& (Io_i^* \neq Io_i)\}.$$

The relation  $[W_i(SIS_i) \rightarrow (SIS_i \cup Io_i)]$  takes place and there is a request  $h^K(Io_i^*(D))$ . This means that we can write  $SIS_i \& W_i \rightarrow \Delta W_i$ , because  $W_i$  is a full description of the subject area of interpretation. So we have  $h^K(Io_i^*(D)) \rightarrow (SIS_i \& \Delta W_i) \rightarrow Io_i^*$ . In the last case the following relation can be written:

$$P_u^M [(W_i(SIS_i) \& Io_i)] \rightarrow [(\Delta W_i \& SIS_i) \rightarrow Io_i^*].$$

The second case that concerns the  $h^K$  user corresponds to solving within the  $SIS_i$  one of  $Zd_i^S$  tasks and is described by the relation (4). Let us assume that  $S_i$  represents a certain  $SIS_j$ . Then the following relation takes place:  $h^K(Io_i(D)) \rightarrow \neg(SIS_j \& Io_i(D))$ . However,  $SIS_i$  and  $SIS_j$  are oriented towards common users  $H^K = \{h_1^K, \dots, h_n^K\}$ . Thus, the relation  $[W_i(SIS_i) \cap W_j(SIS_j)] \neq 0$  takes place. Because  $S_i(SIS_i) \& S_j(SIS_j)$  are structures of the type described in (1), there are common elements in  $S_i(SIS_i) \& S_j(SIS_j)$  connected by implications in  $SIS_i$  and  $SIS_j$ . Fragments:

$$[(Io_{i1}^S, \dots, Io_{im}^S) \in SIS_i] \& [(Io_{j1}^S, \dots, Io_{jk}^S) \in SIS_j]$$

will be called transitions  $PR(SIS_i, SIS_j) = PR_{ij}$  between  $SIS_i$  and  $SIS_j$ . Thus, it can be written that:

$$[W_i(SIS_i) \& W_j(SIS_j) \& PR_{ij} \& (h^K(Io_i(D) \in SIS_i))] \rightarrow Io_i^*,$$

which corresponds to implementation of  $P_u^A$  from (4).

The third case can be described by the following relation between images:  $(Io_i \sim Io_j) = [\neg(Io_i \rightarrow Io_j) \& \neg(Io_j \rightarrow Io_i)]$ . The following relation can be written:

$$\{[(Io_i \& Io_j) \in W_i(SIS_i)] \rightarrow \exists Io_k [(Io_i \rightarrow Io_k \rightarrow Io_j)]\} \rightarrow \{[(Io_i \rightarrow Io_j) \rightarrow Io_k] \vee [(Io_j \rightarrow Io_i) \rightarrow Io_k]\}.$$

The given relation can be extended on any number of  $Io_i \in W_i$  on the basis of the statement (1). This extension allows to write the following relation:

$$[(Io_{i1}, \dots, Io_{in}) \& W_i(SIS_i) \& (\forall Io_{ij} \in W_i)] \rightarrow \{(Io_{i1}, \dots, Io_{in}) \rightarrow [(Io_i \rightarrow Io_j) \vee (Io_j \rightarrow Io_i)]\}.$$

The last conjunct corresponds to the description of the operator action  $P_u^S$  from the relation (5).

When  $h^K(Io_i(D)) \rightarrow \neg[Io_i(D) \& W_i(SIS_i)]$  takes place, it means that  $\forall(SIS_i) \exists(SIS_k) [Io_i(D) \in SIS_k]$  takes place, because if  $h^K(Io_i(D))$  is incorrect, the access system  $SD$  will deny the access and  $SD[h^K(Io_i(D))] \rightarrow \neg(Io_i(D))$ .

If  $\forall(SIS_i) \neg \exists(SIS_k) [Io_i(D) \in SIS_k]$ , then according to the rule (2) for  $h^V$ , a  $Zd_i^S$  is initiated like:  $h^V(Io_i(D)) \rightarrow (Io_i(D) \cup SIS_k)$ .

The above-given proof shows that the system  $\mathcal{P}(SIS)$  ensures the implementation of all  $Zd_i^S \in SIS$ , where  $SIS = \{SIS_1, \dots, SIS_n\}$ .

## 4. Summary

The paper reviewed the task of refreshing  $SIS$ , that consists of regular data actualization, removing from the  $SIS$  the data which are no longer relevant and modifying the data, that represents processes of changes occurring in the environment serviced by the  $SIS$ . The introduced utilization parameters allows to detect and then to eliminate anomalies that occur in the  $SIS$  for various reasons and can lead to failure of solving the necessary tasks by using the  $SIS$ .

The possibility of data refreshment ensures the possibility of using a system of  $SIS$  type regardless of the basic tools used to create each of the single  $SIS$ , because  $SIS$  refreshing functions are implemented by a separate  $SUD$  system that interacts with the  $SIS$  through its user interfaces. Thanks to this, regardless of the natural aging of the  $SIS$  system, it can be effectively used when solving social tasks.
